The other consequence is that child labor is more common in agriculture than in any other occupation. In many third world countries, children drop out of school or never turn up there because their work is needed in the fields. Even in industrial countries where child work on industrial workplaces has been almost completely abolished, young children can be found working on family farms with dangerous machines and animals. In the United States, children as young as 4 or 5 have been found driving a tractor alone (Frank et al. 2004). Hundreds of thousands of the agricultural workers in the United States are immigrant children, some of them as young as 7 or 8 years old, who work under conditions similar to those found in the third world. Many of them work with sharp tools and dangerous machines. Green tobacco sickness, i.e., nicotine poisoning due to dermal absorption from tobacco plants, is particularly damaging to children's health, and the same applies to pesticide exposure (Human Rights Watch 2010). Due to idyllic misperceptions of farmwork, in the United States and elsewhere, the public tolerance of child work seems to be higher if it takes place in farms than in other sectors. *The third challenge is to protect children from work and workplace dangers in*

agriculture in spite of the fact that they live on agricultural workplaces and are brought up in a tradition where child labor is considered normal.

A large proportion of the farmworkers who are not self-employed are instead hired on a temporary or seasonal basis. Workers with uncertain employment tend to consider themselves not to be in a position to make demands or refuse dangerous work. They are also more seldom unionized than workers with permanent employment. This means that in many countries, most agricultural work is done by either self-employed or temporary workers, two groups that are mostly unorganized. In agriculture, trade unions have often failed to play the important role as promoters of workplace health and safety that they have in industrial workplaces.

In many countries, a large part of the agricultural workers are immigrants with less legal protection than citizens. The United States has been estimated to have between three and five million migrant farmworkers, about 80% of whom have immigrant status. A typical attitude among them to unsatisfactory working conditions is that “nothing can be done about it” (Magaña and Hovey 2003). *The fourth challenge is to ensure that the health of migrant and temporary workers in agriculture is fully protected, in spite of their uncertain status that makes many of them unwilling to make demands or to have contact with authorities.*

Agricultural products are commonly used as textbook examples of the advantages of free trade. It does not seem rational for farmers in a subarctic climate to grow oranges in heated greenhouses when these fruits can instead be imported from countries where they grow in the fields. But trade in agricultural products is far from free. Current trade agreements tend to require openness in developing countries while at the same time institutionalizing the subsidies and protections that industrialized countries have created for their own agricultural sector (Gonzalez 2002). The demands of fairness combine with those of economic rationality to support the rectification of such asymmetries. On the other hand, it is not unproblematic to transfer agricultural production from countries with acceptable working conditions to countries with dangerous and oppressive

conditions. The fifth challenge is to combine trade policies with health and safety policies in ways that are beneficial to the underprivileged farmers and farmworkers in developing countries.

Summary

Both in industrialized and developing countries, agriculture is more dangerous than most other occupations. Accidents with animals, tools, and vehicles are common, and a wide variety of occupational diseases result from chemical and biological exposures. Pesticide poisonings are a particularly serious problem in many developing countries. Children are directly exposed to many of the hazards in agriculture, partly because they are used as workers, partly because they live on farms. Many farmworkers are either self-employed or migrant, two categories of workers that are seldom well organized and often have difficulties in getting heard. The health and safety of poor farmworkers and their families is a neglected problem in need of much more attention throughout the world.

Introduction

Organic food is produced without the use of synthetic fertilizers and pesticides. Four further exclusions in organic production are: genetically modified organisms (GMOs), irradiation, prophylactic antibiotics, and engineered nanoparticles. These six exclusions differentiate organic agriculture from chemical agriculture.

Agriculture and food harvesting and production date back millennia, and until about a century ago that history is *de facto* organic. The Industrial Revolution ushered in an era of novel production strategies. Agriculture was not immune to new views of industrialization and reductionism. Advances in chemistry enabled some implementation of such views.

Early in the diffusion of chemical farming practices, the Austrian mystic Rudolf Steiner (1865–1924) called for a differentiated agriculture free of these new synthetic chemical inputs (Paull 2011a; Steiner 1924). The terminology, theory, and practices of biodynamic agriculture evolved (in the 1920s and 1930s) from Steiner's Agriculture Course of 1924. It was a guided evolution, coordinated by Ehrenfried Pfeiffer (1899–1961) in Switzerland.

The UK agriculturist, Lord Northbourne (1896–1982), invited Pfeiffer to lead a conference on biodynamics at his farm in Kent (in 1939). The following year Northbourne published his manifesto of organic farming, "Look to the Land." In that book, he coined the term "organic farming" and wrote of a contest of "organic versus chemical farming" (Northbourne 1940; Paull 2014).

The ideas and ideals of organic farming quickly proliferated internationally off the back of Northbourne's (1940) book. Organic farming is now practiced in at least 179 countries, accounts for 50.9 million agricultural hectares, and a market value of US\$ 81.6 billion (€75 billion) (Willer and Lernoud 2017).

Chemical Disruption

After multiple millennia of *de facto* organic agriculture, the Industrial Revolution, prompted

speculation about revolutionizing agriculture. One British commentator boldly predicted that "we may abolish the old practices and replace them by simpler agriculture, more manageable and more remunerative. Instead of, by great care and precaution, maintaining the fertility of the soil, we reconstitute it ... The soil is merely a medium of production, in which we convert at pleasure the four agents in the formation of plants into this or that crop as suits us" (Riddle 1868, p. 13).

Through the nineteenth century, such reductionist views of chemical advocates remained little more than a thought bubble. It remained so until 1909 when two German chemists Fritz Haber (1868–1934) and Carl Bosch (1874–1940) demonstrated a method of "fixing" nitrogen from the air, that is converting atmospheric nitrogen (N_2) into ammonia (NH_3). The Haber–Bosch process was promptly ramped up to industrial scale production and produced explosives throughout World War 1 (and thereby prolonged it). Once the war was over, the industrial output of synthetic nitrogenous chemicals was repurposed as new cheap fertilizer.

Pushback

The intrusion, on a grand scale, of synthetic fertilizers into agriculture was swiftly met with a pushback from some, including a group of German farmers who convinced Dr. Rudolf Steiner (1865–1924) to throw some spiritual light on the subject. Steiner presented a series of eight lectures on what his philosophical movement, which he called "anthroposophy," had to say on the subject of agriculture. He characterized a farm as an "organism." Steiner outlined his suggestions for a differentiated nonchemical-dependant agriculture. At those lectures at Koberwitz (now Kobyierzyce, Poland), Steiner founded an Experimental Circle of like-minded farmers to test, progress, and publish his ideas.

This Experimental Circle of Anthroposophic Farmers and Gardeners was the world's original organic agriculture research institution. There were three tangible outcomes from the group:

the term “biodynamic farming” was coined to describe this new differentiated agriculture; a certification mark “Demeter” was developed to distinguish biodynamic produce; and Pfeiffer’s book “Biodynamic Farming and Gardening” was published simultaneously in five languages (English, German, Dutch, French, and Italian) in 1938 (Paull 2011c).

In the UK, perennialist and agriculturist Lord Northbourne was impressed with Pfeiffer’s work. Northbourne invited Pfeiffer to present a biodynamics conference to farmers in Britain. One of Pfeiffer’s lectures was titled “The Farm as a Biological Organism.” The nine day Betteshanger Conference was held at Northbourne’s farm in Kent. The audience comprised farmers, gardeners, and academics (Paull 2011b).

The Betteshanger Conference came to a close in the shadow of WW2. The outbreak of war shut off the immediate opportunities for further close collaboration with these continental biodynamics advocates. War with Germany also meant that the British taste for Germanic ideas evaporated. Nevertheless, Northbourne was enthused with these new ideas and his enthusiasm was in no way dampened. He probably also realized that Pfeiffer, while an inspired agriculturalist and speaker, was not an inspired writer.

Northbourne published his own book “Look to the Land” (1940). It was a ground-breaking book, his best and clearest, a manifesto of what he coined as “organic farming” (extrapolated from Steiner’s expression “the farm as organism”). Northbourne made a powerful and eloquent case for his “organic farming,” and he presented that advocacy in the context of a contest that he termed “organic versus chemical farming.”

Values

From the outset, advocacy for organics was driven primarily by values rather than agroeconomics. The decades of advocacy that have followed since “Look to the Land” first appeared, have been underpinned by the foundational ethic that we cannot poison our way to health and prosperity.

Northbourne was an articulate advocate for organics. He argued in his book against monocultural agriculture, preferring biodiverse farming. He argued against a chemical reductionist approach to farming. He asserted that “No chemist has ever analysed or described in chemical terms a living creature, however humble; and there is not the slightest chance that he ever will” (1940).

“Look to the Land” argued for engaging the precautionary principle. Northbourne argued for a holistic view. He warned: “Farming cannot be treated as a mixture of chemistry and cost accountancy, nor can it be pulled into conformity with the exigencies of modern business, in which speed, cheapness, and standardizing count most. Nature will not be driven. If you try, she hits back slowly, but very hard.”

Traction

Northbourne published his organics manifesto in the early years of World War II. Violent conflict and destructive forces were engulfing the globe. And yet, he offered this gentle message for agriculture: “We have tried to conquer nature by force and by intellect. It now remains for us to try the way of love.” Northbourne’s views were swiftly taken up as far away as USA and Australia.

In the USA, publishing entrepreneur Jerome Rodale (1898–1971) embraced Northbourne’s ideas and launched a new magazine “Organic Farming and Gardening” (in 1942). It was the world’s first periodical to champion organic agriculture. Over more than eight decades and through multiple iterations of format and name variations, Rodale’s periodical has been the world’s most successful organics publishing venture.

In Australia, grazier Colonel Harold White (1883–1971) and colleagues founded the Australian Organic Farming and Gardening Society (1944–1955). This was the world’s first association dedicated to promoting organic agriculture. The society published their own periodical “Organic Farming Digest” drawing on both local and international sources.

Associations dedicated to promoting organic agriculture generally struggled to stay afloat in the early decades. Their financial underpinnings were insecure until the advent of organic certification (developed mostly from the 1980s onward). Certification provided customers with an assurance that what they were purchasing really was organic. It enabled the internationalizing of a validated organics trade between nations. Certification also laid an economic foundation for organics advocacy groups. Globally, there are now hundreds of organics certifiers, with many countries having multiple certifiers.

Price Premium

When you purchase organic food you probably will pay more than for a comparable product of chemical agriculture. And when you purchase organic food you are paying for some things you do not get. In particular, you do not get the sequelae of synthetic fertilizers, pesticides, GMOs, irradiation, antibiotics, and engineered nanoparticles. To avoid these things, you will have paid a premium, most typically a premium of somewhere between 10% and 100%.

The price premium for organic food is an impediment to the growth of the sector. Some consumers are seeking food options with the cheapest price tags, perhaps because their budget is tight, while for others the production methods are matters beyond their concern.

We know from multiple studies that consumers purchase organic food for reasons of health, environment, and animal welfare (e.g., ACNielsen 2005). A study of 21,261 consumers in 38 countries reported that 72% of consumers purchase organic food, either “regularly” or “sometimes” (ACNielsen 2005). The main reasons consumers nominated for purchasing organic food were: “healthier for me” (51%), “healthier for my children” (17%), “better for the environment” (15%), “kinder to animals” (7%), and “other” (10%) (ACNielsen 2005).

We know that “organic” is an important food selection criteria for a substantial number of

consumers (e.g., GfK 2017). A global survey of more than 23,000 consumers in 17 countries revealed that “organic” was important for many in making their food choices (GfK 2017). Respondents were asked “When deciding which food or beverage product to eat or drink, how important are the following in making your decision?” Globally, 44% of respondents rated “organic” as “very important” or “extremely important.” The Netherlands, UK, and Canada reported the lowest percentages of consumers rating organic as very or extremely important (22%, 24%, and 26%, respectively). China, Russia, and Brazil reported the highest percentages of consumers rating organic as very or extremely important (58%, 52%, and 49%, respectively) (Fig. 1) (GfK 2017).

Externalities

It is generally claimed that organic production costs more than chemical agriculture. The productivity of organic agriculture may be between 0% and 10% less than that of chemical agriculture (although the micronutrients will be denser in organic food). Labor input costs may be more for organics (for example, because of manual or physical weeding rather than applying herbicides). Chemical input costs are expected to be higher for chemical agriculture (the bill for agrochemicals may be for pesticides including herbicides, fungicides, insecticides, rodenticides, bactericides, etc.).

However, some costs of chemical production are not included in the shelf price of the food item. This is because there are externalities of chemical agriculture that are not sheeted back into the shelf price of products but rather they are borne by the community. The “tragedy of the commons” is that pollution and damage to the commons is often not billed to the polluter (rather than polluter pays).

Chemical production degrades and depletes the soil (in contrast, organic production enriches it). Chemical inputs are not contained within the farm. Fertilizer runoff can pass into streams and rivers and ultimately into the ocean. This can lead to fertilizer-induced eutrophication and algal blooms, and then, as the oxygen is depleted, to

Organic Food and Agriculture, Fig. 1 Percentage of consumers who rated “organic” as important for their food choices (Data source: GfK 2017)

dead zones. (The biggest dead zone is in the Gulf of Mexico, where agricultural nutrient runoff carried in by the Mississippi River has created a massive hypoxic zone of over 20,000 km²).

Pesticides escape from farms. Some remain on food, and some of that pollution is consumed. Some pesticides damage nontarget species. Biodiversity is reduced under chemical-intensive monocultural agriculture.

In chemical agriculture, the costs and harms of pollution are distributed across the commonwealth. The noncontainment and the ingestion of pesticides damage the health of consumers, farmers, wildlife, and the environment. If such externalities (uncosted harms) are included into the production financial matrix then organic production is demonstrably less than chemical production (Seada et al. 2016).

War and Equipoise

Chemical agriculture advocates are fond of invoking a “war on pests and weeds” and issuing calls to “help us to win the war” (e.g., Joyce 2016). Such a war is a perpetual war, with no possible end in sight, a war that is in no way winnable. An extermination of “pests and weeds” would herald an

ecological catastrophe. A healthy ecosystem relies on biodiversity and a myriad of interactions and interdependencies. An invoked “war on pests and weeds” is not a war that we need to wage, and it is not a war that we would want to win.

Organic agriculture offers a viable alternative to agricultural warfare. It advocates biodiversity and complexity rather than monoculture and eco-simplification. Biodiversity is an insurance policy for ongoing global food security. Organic agriculture offers the well-being of the commonwealth, as an alternative to corporate enrichment at the cost of an impoverishment of the environment and the degradation of the commonwealth.

Organic agriculture has always focused on giving consideration to the environment. Yes, it has valorized “natural.” And yes, it has, on occasion, anthropomorphized nature; an example is the UK Soil Association journal “Mother Earth.”

Organic farmers have fought the US government to halt the indiscriminate aerial spraying of DDT and three of them informed Rachel Carson’s “Silent Spring” (Paull 2013). Organics advocates have regarded the view that we can poison the planet with impunity and without adverse and perverse consequences as a grand delusion. Organics advocates have sought equipoise with nature rather than war with nature.

IFOAM: Organics International

Organics advocate Roland Chevriot, President of the French “Nature et Progrès” proposed in 1972, an international umbrella organics advocacy group. From a broad mail drop of invitations to a meeting that he convened in Versailles, France, five organizations attended.

It was an international congregation with five countries represented (France, South Africa, Sweden, UK, and USA). None of the five organizations that came together in Versailles had “organic” in their title. Nevertheless, the name (in English) proposed by Chevriot in his letter of invitation to delegates, the “International Federation of Organic Agriculture Movements” (IFOAM) was adopted.

The Versailles meeting cemented “organic” as the key term uniting these disparate groups and collectively differentiating them from others. The founding of IFOAM reiterated that organic agriculture was an international endeavor, that there was an embrace of diversity under the umbrella, and that biodynamics was a fully fledged variety of organics. (One of the five founding members was the Swedish Biodynamic Association).

The headquarters of IFOAM is now in Bonn, Germany. There are 833 affiliates (members, associates, and supporters) from 121 countries (Willer and Lernoud 2017). IFOAM recently revised its somewhat cumbersome name and discordant acronym to rebadge itself as “IFOAM – Organics International.” It thereby retains a vestigial link to the original vision of an “International Federation of Organic Agriculture Movements.” The web address of IFOAM – Organics International is “www.ifoam.bio” which reflects that “organic” is known as “bio” in many European markets.

Peri-Organics

There are production systems that are organics fellow-travelers which do not necessarily meet the requirements for organic certification. Green Food in China is a certification system that is

many times bigger than certified organic in China. Green Food is a certified production system of reduced chemical inputs. It can offer a stepping-stone for Green Food farms to convert to organic.

There are pesticide free (or nearly so) production systems that are monocultural, hydroponic, and with controlled atmosphere (e.g., tomato production at Sundrop Farms in Port Augusta, South Australia, and expanding to Portugal and USA). Under the prevailing organic standards, organic certification is not available to such a production system although it may meet many consumer expectations of organic produce.

The Slow Food movement champions local production, local varieties, local food culture, traditional agriculture, and traditional cuisine. Organic production is a favored methodology within Slow Food without being mandated.

All organic production is GM-free, but not vice versa. GM-free is a necessary but not sufficient criterion for organics certification, but it remains a suitable stepping-stone to organic conversion for those who want to make the additional commitments.

Growth

Organic agriculture is a niche agriculture aspiring to be the dominant agriculture of the world. The reality-check is that certified organic agriculture accounts for just 1.1% of global agricultural land. To this modest statistic, uncertified organic agriculture might be expected to add several additional percentage points, perhaps to double, triple, or quadruple it. However, there are no statistics for this notional uncertified organic agriculture sector. Food producers may be uncertified for a spectrum of reasons, particularly, because of the small scale of their operation and/or the cost and availability of certification

For the past two decades, organic agriculture has been growing at 12% per year (measured by certified organic hectares). Nevertheless, the sector is a long way short of the 100% that it aspires to. The path to that “otopia” of 100% organic is an unformed untrod track.

The north eastern Indian state of Sikkim provides a roadmap for achieving 100% organic. The state set the ambitious goal, in 2003, of converting to all-organic agriculture. This goal was achieved in 2016. At least four other states of India have expressed their goals of following Sikkim's lead. The nearby country of Bhutan has stated its ambition to be the first country to be 100% organic (Paull 2017).

Conclusion

Organic agriculture has always been presented as an ethical solution to the great task of feeding the world in a healthy and sustainable manner. It has never been seen as a “quick fix.” Organic agriculture is in active contestation with chemical agriculture. This has always been an asymmetric contest of big and aggregated chemical company interests and profits versus the values and ethics of broadly dispersed concerned citizens and farmers.

The reconquest of global agriculture by the organics movement was always foreseen as a long campaign. Northbourne was under no illusions when he declared that: “It is a task for generations ... for many decades, perhaps for centuries” (1940).

The dharma of the food production system is to provide healthy nutrition for the community. The core message of Northbourne in his manifesto of organic agriculture is that “Farming cannot be treated as a mixture of chemistry and cost accountancy.” That would be a false path and a wrong ethic on which to base community health and well-being. Organic agriculture is a proven solution for meeting the brief of providing healthy nutrition for the prosperity and well-being of the community.

Organic Food Policy

Lisa F. Clark

Department of Agricultural and Resource Economics, College of Agriculture and Bioresources, University of Saskatchewan, Saskatoon, SK, Canada

Introduction

Food labeled as organic has been produced and consumed for almost a century, but it is only since the late 1990s that organic food policy – a series of policies regulating organic labels and certifying inorganic food production – has become part of public policy frameworks in North America, Europe, and other countries like Australia and Japan. Generally speaking, organic food policy (more generally organic agriculture policy) outlines the rules, standards, and regulations guiding certified organic (“organic”) production of all products labeled certified organic including but not limited to foods like fruit, vegetables, nuts, and animal-derived products like eggs and meat. Production processes for wine and other beverages can also be certified. This article focuses specifically on discussing organic agriculture policy as it applies to food products (organic food policy). It discusses the origins of organic food policy and its basis on a set of principles developed since the 1940s. It also explains the development of organic food policy and how it emerged from the charters and guidelines penned by organic producer organizations and international organizations like *The Soil Association*. The essay also discusses some of the issues surrounding the evolution of organic food policy and other contentious issues that have accompanied its development.

Foundations of Organic Food Policy

Principles of Organic Agriculture

The industrializing processes of agriculture in North America and Europe in the immediate post-war period were successful at securing high yields of staple crops and reducing the costs of food passed onto the consumer to feed growing populations. The use of chemical inputs like petrol-based fertilizers and pesticides, as well as practicing monoculture, contributed to achieving higher yields and producing crops at a faster rate. But some questioned this model of agriculture’s reliance on fossil fuels, specifically the reliance on chemical inputs to balance the macronutrients NPK (nitrogen, phosphorus, and potassium) in the soil necessary to produce healthy crops, as well as the reliance on chemical pesticides. Some thought that a model of food production relying on chemical inputs was harmful to soil fertility and environmentally unsustainable. Critics of industrializing processes argued that it was possible to enrich the soil using recycled on-farm inputs. Scientists like Briton Sir Albert Howard experimented with using on-farm wastes like manure, compost, and humus to return macronutrients to the soil without the use of synthetic inputs to produce food. Though pioneers like Howard did not call his experimental methods “organic,” these agricultural practices of recycling on-farm wastes to maintain the macronutrient health of the soil with limited reliance on off-farm inputs created the foundation for the principles of organic agriculture that ultimately became key components of organic food policy decades later (Conford 2001).

The early success of agricultural techniques that would later become known as organic drew a growing following of practitioners and supporters across Europe and in other parts of the world in the 1940s. Supporters felt that chemical inputs used in what would be referred to as “conventional” agriculture harmed the health of the soil and affected the nutritious qualities of food, which ultimately affected human health. The spread of knowledge of organic techniques and their claimed benefits helped to form organizations all over the world devoted to promoting

organic agriculture as a viable alternative to industrialized food production methods. Howard and fellow organic agriculture supporter Lady Eve Balfour formed *The Soil Association* in Britain in 1946. J. I. Rodale, who is credited with introducing organic agriculture to the USA, established an experimental farm in Pennsylvania called *The Soil and Health Institute* in 1946. These organizations would develop organic standards and would become the first certifiers for producer operations practicing organic methods (Rodale Institute 2012). Organizations would form the social and political foundations for the organic agriculture movement and would serve as sources of information for producer organizations that would pen their own organic guidelines and principles.

Early Organic Producer Organizations

Historically, organic production and product standards were developed and administered by local producer organizations and focused on agricultural techniques that maintained and nurtured the health of the soil based on local climate and geographic conditions. Local producer organizations in Europe and North America developed codes of conduct and lists of allowable processes for producers to abide by in order to label their products “organic.” In the early days of the organic movement, most producers sold their organic products at farmers’ markets or sold their products to local health food stores or other food retail outlets. The number of links in early organic food chains was few, and most organic food products circulated in local markets. This model of localized market interactions involving people who personally knew each other would become associated with the emerging organic movement. Personal relationships between farmers and consumers would become an important part of what distinguished organic agriculture from the conventional model that was criticized as distancing people from the food system through mechanization. Most organic agricultural associations were premised on developing a self-sufficient form of food production that did not involve government or “agribusiness,” the latter of which many organic practitioners viewed as benefitting from industrialized

agriculture with little concern for the negative environmental outcomes associated with an over-reliance on chemical inputs.

Emergence of Organic Standards

The first set of organic production standards were penned by the Soil Association in 1967. They were published as a four-page set of guidelines instructing practitioners to avoid using any inputs that could harm “microorganic” life in the soil. The standards also prohibited routine use of antibiotics in livestock and the use of chemical pesticides. The Soil Association also requested that each of its members sign a document stating that they would abide by the Soil Association’s standard for organic agriculture.

Subsequently, local producer organizations emerged that devised standards and guidelines reflecting the ecological realities of local production (Soil Association 2016). Some producer groups specified that members should practice crop rotation and polyculture to manage pests and combat plant diseases to avoid using chemical inputs. Though traditionally resistant to government intervention of any kind, early organic producers developed detailed production standards that would eventually serve as a basis for organic food policy frameworks in the 1990s. Some associations also became certification bodies that would later become accredited organic certification operations.

One of the main factors that led to growing consumer demand for organic food was the increasing attention paid to the environmental damage attributed to conventional agriculture and growing public awareness of the links between health, nutrition, and food. The environmental (or green) movement emerged in the 1960s, which criticized the damaging effects of industrialization on human and environmental health. Rachel Carson’s book, *Silent Spring* (1962), spearheaded the environmental movement in the USA by chronicling the decline of songbirds due to the overuse of industrial pesticides. Because organic agriculture did not use industrial pesticides that were associated with environmental damage, it quickly became associated with the environmental movement.

The association of organic food with a “chemical-free” way of producing food emerged in the mainstream as people became increasingly aware of the effects pollution was having on the environment. Since organic agriculture purposefully rejected products used in conventional agriculture like synthetic fertilizers and pesticides, it became associated with environmentalism and sustainable agricultural practices. Some practitioners of organic agriculture also rejected the involvement and control agribusiness exerted in the industrializing processes associated with conventional agriculture. The involvement of agribusiness was argued to be the cause of the decline of the family farm, rural culture, and farming livelihoods (Berry 1977). Since organic agriculture defined itself as distinctly different from conventional agriculture, organic practitioners distanced themselves from the institutions and economic structures in the conventional food system.

Governmental policymakers largely ignored organic agriculture until consumer demand for organic food began to grow. A system of monitoring and certification became increasingly necessary to verify that foods carrying the organic label were produced in accordance to organic principles. Standards and certification systems would also deter fraudulent claims of organic, which were distinct possibilities as organic foods routinely garner a premium price compared to conventional fare, and it is almost impossible to determine whether a food product is produced in accordance with organic principles based on inspection of its physical attributes (Ikerd 1999). Therefore, as the distances organic foods traveled between producer and consumer grew, so too did the need for enforceable public standards to regulate production processes and labeling requirements.

What Is Organic Food Policy?

Beginning in the late 1980s, government agriculture and food agencies began to develop rules and standards for organic agricultural production, which include policies specifically directed at

food production methods. The first country to pass organic certification standards was Germany in 1985. Since the 1990s, many countries (and political-economic unions) have passed national organic standards beginning with the European Union in 1991 (EC 2007), which is the biggest market for organic food products in the world. The second largest market for organic products, the USA, passed its organic standards in 2000 (USDA 2002). But not before a historic controversy almost completely derailed the entire standards-setting process.

One of the biggest controversies in organic food policy history is what the drafted National Organic Program rule released by the United States Department of Agriculture (USDA) in 1997 did *not* contain. By the late 1990s, the market for organic food both within the USA and around the world was expanding rapidly. Consumer demand for a wider variety of organic foods was growing, and without a government-sanctioned set of rules and principles to regulate organic agricultural processes, the US market would stagnate. After a lengthy consultative process beginning in 1992, the *National Organic Standards Board* consisting of US-based organic practitioners, advocates, and industry associations presented the USDA with a draft National Organic Standard. The exemptions and edits that the USDA made to the draft NOP before it was released for public comment caused shockwaves across the organic industry. Left out from the USDA version of the NOP were restrictions on the use of GMOs, bio-sludge, and irradiation in certified organic production (Baker 2004). The USDA version of the NOP was in response to concerns voiced from the conventional food sector that objected to any language in USDA regulations that negatively portrays other types of food production, specifically the use of biotechnology in the food system.

The omission of GMOs from restricted substances led to a massive public outcry. The USDA received over 275,000 complaints from the public, the largest number of comments on one piece of regulation that the USDA had ever received. The amended version of the NOP, which went into effect in 2000, did restrict the use of

GMOs in certified organic operations. Organic operations are required to declare that they have not used GMOs in production processes and have taken steps to avoid contact with GMOs. Other notable countries passing organic standards that also restricted the use of GMOs include Japan in 2001 (MAFF 2007) and Australia (Australian Organic 2013) & Canada (CGSB 2006) in 2009.

Depending on the country, governmental departments or agencies are responsible for writing and revising the standards covering organic production. Before revising, many governmental agencies consult representatives from relevant stakeholder associations such as the International Federation of Organic Agricultural Movements (IFOAM), the Organic Trade Association, and the Organic Consumers Association. Individual countries are responsible for enforcement. For example, individual countries in the EU are responsible for enforcing the EU organic standards and certification activities within their borders. Germany's Federal Ministry of Food and Agriculture enforces the Germany Organic Farming Act, which transposes the EU level legislation into German law. In the USA, organic standards and certification requirements are handled by the USDA, and in Japan, organic standards are under the jurisdiction of the Ministry of Agriculture, Forestry and Fisheries.

Organic food policy frameworks also contain lists of organizations that are government-sanctioned accreditors. Accreditation is the authority given to certifying associations to inspect, monitor, and certify producers, processors, and handlers as "certified organic." Certification agencies verify that organic operations are following the regulations outlined in organic food policy and respecting the restrictions on the permitted substances list and are following proper handling and storage guidelines. Farms can only be certified if the soil is free from restricted chemical input use for a period of time, usually 3 years. Certified operations are inspected and audited by the accreditation organizations to insure they are maintaining the standards. If an operation is found to be in violation of any of the regulations or standards, they can be decertified. Examples of accreditation organizations recognized in organic

food policy are the California Certified Organic Farmers (USA), Naturland (Germany), Eco-Cert (France), Australian Certified Organic (AU), and the Canadian Seed Institute (CA). Several of certification agencies, like Eco-Cert, certify operations in multiple jurisdictions like France, Japan, and Canada.

Production Standards

Official production standards can come in many forms. Generally, they cover handling and storage requirements, certification, labeling, accreditation guidelines for certifying agents, and allowable substances related to organic agriculture and food products. For example, Australia has one document, *the Australian Certified Organic Standard 2013* (Australian Organic 2013), that covers all aspects of certification. The USA also has one piece of legislation (the Organic Foods Production Act) that covers all of the stipulations and guidelines that US-based organic operations must follow. It, like standards in other jurisdictions, also applies to all imported products sold as certified organic within the country. Japan has three sets of policy documents covering organic standards, technical criteria for certification, and inspection methods (MAFF 2007). Some countries have additional rules, standards, and restrictions concerning organic practices and procedures. For example, some regulations include guidelines for the treatment of organically raised animals and restrict the use of specific food additives in processed certified organic foods. The Canadian organic standards called the *Canadian Organic Standards* (COS), in its preamble, explicitly mentions the "humane treatment of animals" as an integral part of organic agriculture. Section 6.1.3 of the COS requires herbivore livestock to have access to pasture during the grazing season (weather permitting) and access to "open air." This is similarly stated in EU regulations (Clark 2015).

Permitted Substances

In addition to regulating how organic foods are produced and outlining accreditation guidelines, regulatory frameworks for organic food also contain lists or specifications regarding "allowable

inputs” or permitted substances that can be used by certified operations. Each jurisdiction’s lists are slightly varied, but none of them permit the use of GMOs in certified organic agriculture under any conditions. Since organic agricultural techniques are based on the principle of restricting chemical or industrial inputs like synthetic or petroleum-based pesticides, herbicides, fungicides, or genetically modified organisms, certified operations must strictly adhere to the restrictions on inputs. The Canadian organic standards have a separate policy document outlining allowable inputs called the Permitted Substances List (CGSB 2006). Some permitted substances used in certified organic agriculture and food processing are also used by conventional operations. For example, gypsum (calcium sulfate) is an allowable substance on permitted substances lists, which is used as a fertilizer to correct calcium and sulfur deficiencies in the soil. Gypsum is not considered a synthetic input because it is a mined mineral. In the EU legislation, sodium nitrate and potassium nitrate are allowable inputs for cured organic meats under its permitted food additives and processed aids section of the legislation. All of these permitted substances included in organic food policy are also permitted in conventional food production and processing.

Labeling

An important part of organic food policy is the sets of regulations pertaining to organic food labels. Each jurisdiction has specific guidelines for what food products can carry the “certified organic” label. In Canada, food products with 95 % certified organic ingredients or higher can only carry the certified organic label in Canada (CFIA 2015). For multi-ingredient products, each organic ingredient must be indicated as such. In the USA, for example, a certified organic food product can carry a “100 % organic,” “certified organic” (with an allowance of 5 % nonorganic ingredients), or “made with organic” (a minimum of 70 % organic ingredients) label; none of the ingredients (even the nonorganic ones) are permitted to use genetic engineering (USDA 2002). In Australia, food products can carry a “100 %

organic” or a “95 % organic” label, but the remaining ingredients must not contain GMOs or use irradiation (Australian Organic 2013).

Rejection of “Certified” Organic

The institutionalization of organic standards into conventional regulatory structures has benefited many actors engaged in the organic sector. It has added legitimacy to organic food labels and aided many producers to convert to organic agriculture. It has expanded markets for domestically produced certified organic products, which has contributed to economic growth. But the formalization of organic food policy is not without its critics. Some organic practitioners have rejected the institutionalized version of organic principles into formal standards and guidelines arguing that it has watered down the standards that have been part of organic agricultural practices for decades. Some practitioners think that national organic standards do not go far enough in terms of requiring organic producers to farm on a small scale, which is argued by some to be the only model of organic farming that can recycle on-farm waste in a sustainable way, while remaining environmentally sensitive. As such, some opted out of the certification process though they maintain and adhere to organic principles and agricultural practices. Some organic farmers continue to farm on a small scale and prioritize the health of the soil and continue to experiment with innovative ways to reduce off-farm inputs (e.g., no-till farming techniques) despite no explicit mention of farm size in organic standards.

There are groups around the world that reject organic food policy and instead label their organically produced (but not certified) products as “authentic” (Esch 2013). There is also a growing movement in the USA to create a “certified natural” food labeling system, where food is produced without using synthetic chemical inputs, inspected by peer farmers and distributed in local markets. This approach in protest to the “government takeover” of the organic program in the USA exhibits many of the same qualities found in early organic producer associations in the 1960s that reject government involvement.

Equivalency Arrangements

In addition to organic certification standards covering domestic production and domestically sold organic products, several countries have entered into equivalency agreements. National regulations covering organic production practices and organic food labels are not only developed to maintain the integrity of the certified organic label, but they are also meant to facilitate trade among partners. Bilateral organic standards equivalency agreements (officially called equivalency arrangements) have the purpose of recognizing the equivalence of organic certification requirements to eliminate or reduce duplication of inspections, certifications, or the need for businesses to obtain import permits. Ultimately, they help ease the movement of certified organic products across borders. Through equivalency agreements, nationally certified organic food labels are recognized as legitimate in the domestic markets of the signatories. For example, the US-EU arrangement establishes mutual recognition of each signatory's organic production rules and control systems as equivalent. Organic products certified in the USA or the EU are legally allowed to be sold as certified organic in each respective domestic market. Bilateral equivalency agreements exist between the following countries: Canada, the USA, the EU, Japan, and Australia. As of early 2016, South Korea has equivalency agreements with all of the countries listed above with the exception of Canada.

Bilateral equivalency agreements for organic standards and guidelines help to reduce overlap and policy redundancies that disrupt or slow the movement of organic foods and other products across borders. Equivalency arrangements are beneficial to domestic operations wishing to have access to global markets without duplication of certification or accreditation requirements that can be quite costly. Consumers also reap the benefits of access to a wider variety of internationally sourced organic products, which can lead to competitive pricing and eventually – in theory – lower prices passed on to the consumer.

Despite the urging of international organic agriculture organizations like IFOAM to move toward global harmonization of organic standards, the countries with the biggest markets for organic products (USA, EU) do not appear to be interested. Equivalency is not a synonym for harmonization. Equivalency means that each country maintains autonomy over the scope of their own organic standards and how they are administered. It also allows for signatory governments to review and amend their own organic standards and allows them to choose which other countries to engage with. For example, countries may choose to only sign equivalency arrangements with countries that have stable political institutions and regulatory structures that have the capacity to inspect, audit, and monitor organic operations to discourage, detect, and eliminate any deviations from the strict standards and guidelines. This is important in terms of food safety but also for the integrity of the certified organic labeling system that is premised on the notion that regulations are upheld, respected, and enforced.

The downside of pursuing equivalence over harmonization is that countries outside of equivalency agreements are excluded. If they want access to those markets (which happen to be the biggest markets), exporters are subject to attaining third-party certification, which is recognized in the importing country or import permits, which could be prohibitively costly for many businesses in the developing world. The global expansion of the organic market has meant that there are growing economic opportunities for developing countries to participate in the global trade in organics. IFOAM has attempted to encourage the move toward harmonization, arguing that a global agreement on standards for organic agriculture could be beneficial for developing countries that have products to offer the global market and would encourage the further expansion of organic agriculture around the world. But critics of the harmonization position argue that it may be problematic to import products from abroad that do not meet the domestic standards for organic production that may exceed a globally harmonized standard. Countries like Canada, the USA, Japan, and the EU also have vested interests in nurturing

their own organic food sectors that contribute billions of dollars every year to domestic economies. Though equivalence arrangements are an important step toward facilitating the expansion of the global market for certified organic foods, the majority of them are between advanced countries.

Conclusion

This essay has traced the evolution of organic food policy from its humble beginnings as local organic producer association codes of conduct to formalized regulation and bases of trade arrangements. Organic food policy includes many of the elements found in early producer association guidelines like certification, permitted substances, and production process standards. Organic's claims of being an environmentally sensitive alternative to conventional food production has struck a chord with consumers around the world who want to support environmentally sustainable food production practices and do not want to consume GMOs. Some of the more substantive elements associated with the early organic agricultural movement are noticeably absent from the majority of organic food policy frameworks which has caused some to question the motivations behind regulating organic food in its current capacity. Despite organic agriculture's long-time fringe status and its rejection of agribusiness and the conventional food sector, it is now a global multibillion dollar industry that shows no evidence of slowing down.

Introduction

Defining peasant farming is a contentious undertaking, because it has vastly different meanings depending on how it is used and by whom. These different usages are often tied up in deeper ethical questions about the livelihoods of a large subset, if not the entirety, of the human population. Although for some, peasant farming is associated with underdevelopment and misery, for others it means the future. The least common denominator of the divergent definitions is that peasant farming is the cultivation of land for the main purpose to subsist on its products.

Peasant farming cannot be fathomed without understanding the people that are engaged in it. There are two ways to think about what defines the peasantry. One is a mostly academic, in some jurisdictions legal, definition that is applied to people from the outside. The concept of the peasantry as a social class is such an example. From this perspective, we may look at someone's livelihood strategy and their relationship with the means of production and their labor product to determine whether this person is a peasant. The other approach is to inquire about self-attributed identity. We may find people who do not fit into any commonly used classification of peasant, yet they see themselves as just that. This discrepancy may reflect an internalized peasant tradition that clashes with the constraints of the present or it may be an expression of how one would like to live in the future. The next two sections will probe into these two frameworks.

Peasants' as a Social Class within Capitalism: The Agrarian Question

Karl Marx predicted that the peasantry as a social class would disappear with the industrialization of agriculture, making way for agrarian wage workers. This prophecy has sparked a long-standing debate in the social sciences, often referred to as the "agrarian question" (Kautsky 1988), that inquired into the political and economic future of the peasantry in a capitalist

society. One camp argues, in line with Marx, that the peasantry ceases to exist within a capitalist economy, while other scholars are perplexed by what they perceive as the persistence of the peasantry. Karl Kautsky (1988) took somewhat of a middle ground. He acknowledges that peasant farms fulfil important functions within agrarian capitalism, such as providing industrial farms with labor power and producing at lower than average wages. He also recognized the specificity of agriculture in comparison to manufacturing. In agriculture, land is nonreproducible, unlike the means of production in manufacturing. And since peasant farms are mostly oriented toward subsistence, much of their production and many of their inputs are not valorized. Thus, peasants cannot be classified as petty commodity producers and Marx's theory on their disappearance cannot be applied to agriculture. Regardless, Kautsky anticipated that industrial agriculture would eventually supersede peasant farming due to its superior productivity; if not during capitalism, then in socialism.

Henry Bernstein (2010) argues that, today, peasants are fully incorporated in the global capitalist economy and fulfill the roles of workers, petty commodity producers, or small-scale capitalist farmers. Through centuries of dispossession, the enclosure of the commons in particular, peasants have been bereft of the means of their reproduction, their ability to subsist independently from capitalist market relations. If farmers have been able to stay on the land at all, they have become dependent on external capital to provide them with means of production, just like factory workers are provided the means of production and a meager wage by the factory owners in exchange for their labor. Those peasants, who managed to keep control of their farm, started to hire workers from outside, thus becoming capitalists themselves. Many farmers today fulfill both positions, providing means for farming to landless workers while at the same time being dependent on external credit. Within capitalist relations of production, the farming family who owns all its land (or has access to common land) and inputs, and produces for its subsistence as well as petty commodities, becomes the exception that proves the rule.

This line of thinking has been challenged on the grounds that peasant farms behave according to a unique economic rationale that is incompatible with the classical economic theory on which Marx's predictions were built. The first scholar to make this argument was Alexander Chayanov (1986). Marx assumed, that through the capitalization of agriculture, farmers would enter an accumulation race, in which the winners would differentiate from the losers as capitalists and dependent wage workers, respectively. Chayanov showed that peasants had no reason to enter such a race because they were family-run operations. He found that classical economic theory was inapplicable to family farms because no wages are paid and most farm inputs enter the production process as nonvalorized use values instead of priced commodities. Instead of maximizing production, peasant farms aim their annual yield to approach an equilibrium between the consumption needs of the family and the labor necessary to produce it. Once these consumption needs are fulfilled, there is little incentive for more drudgery to increase output. Consequently, a tendency toward accumulation is not a convincing argument for why the peasantry should disappear. Moreover, family farms are able to adjust their consumption levels (self-exploitation) in dire years, and thus continue their operation when other farms become unable to pay wages to their workers. Based on Chayanov's pioneering work, the field of peasant studies emerged in the late 1960s, probing into noncapitalist forms of agricultural production as well as their relationship to capitalism. Veronika Bennholdt-Thomsen and Maria Mies (1999) argue that subsistence producers such as peasants make up one of capitalism's *colonies*, a field whose labor product is constantly appropriated. Since capitalism depends on this reproductive labor for which not even wages are paid, the peasantry continues to exist, despite precarious conditions.

Mann and Dickinson (1978) argue that it is not the ability for self-exploitation that explains the persistence of the peasantry, but the general unsuitability of agriculture as a field of capitalist accumulation. Marx (1977) insisted that only labor time creates value. Yet, in agriculture,

Mann and Dickinson argued, the production time far exceeds labor time, since plants need time to grow beyond the time actual human labor is applied in planting, weeding or applying fertilizer, and harvesting. As a result, the amount of additional surplus value that can be generated by rationalizing the labor process is small, making agriculture unattractive for capital compared to industries with shorter production cycles. This argument, however, failed to take into account that in some agricultural sectors with equally long production cycles, such as industrial fruit and vegetable production, wage labor does indeed prevail.

Peasantry as Identity

The view presented above depends on the definition of the peasantry as a distinct class of landed farmers, derived from Marxian class theory. However, many people in the world claim a peasant identity despite being fully entangled in capitalist relations of production. Vastly diverse in their relations to the means of production, many of them are landless people (with or without gainful work), while others own land and other forms of capital. They share a common identity as peasants, a vision that perhaps is stronger than their opposing class interests. For instance, in its proposed draft for the UN declaration of peasant's right, the international peasant's movement La Via Campesina defines peasants as follows:

A peasant is a man or woman of the land, who has a direct and special relationship with the land and nature through the production of food and/or other agricultural products. Peasants work the land themselves, rely[ing] above all on family labour and other small-scale forms of organizing labour. Peasants are traditionally embedded in their local communities and they take care of local landscapes and of agro-ecological systems. The term peasant can apply to any person engaged in agriculture, cattle-raising, pastoralism, handicrafts-related to agriculture or a related occupation in a rural area. This includes Indigenous people working on the land.

The term peasant also applies to landless. According to the UN Food and Agriculture Organization..., the following categories of people are considered to be landless and are likely to face difficulties in ensuring their livelihood:

1. Agricultural labour households with little or no land;
2. Non-agricultural households in rural areas, with little or no land, whose members are engaged in various activities such as fishing, making crafts for the local market, or providing services;
3. Other rural households of pastoralists, nomads, peasants practicing shifting cultivation, hunters and gatherers, and people with similar livelihoods.

(La Via Campesina 2009)

Here, a peasant identity is evoked not just as an expression of current conditions of life, but as a desire for a future in which class conflicts are resolved at least to the point that “people of the land” can live off the land. It is this identity that many commentators have in mind when they talk about peasant farming. It is a different frame of thinking that does not stand in opposition to the argument over whether the peasantry has ceased to exist as a distinct class within the labor process.

Peasant Values and Ethics

Although many authors who define the peasantry by identity consider peasants as a group with “shared values” (e.g., Van der Ploeg 2008), they do not usually spell out what these values are. Given the large geographic and social diversity of peasants, this is not a surprise. Inquiries about these shared values tend to be local in scope. For instance, James Scott (1976) describes the “moral economy” and “subsistence ethics” of peasant farmers in Southeast Asia. He found that peasants avoid risks that might threaten their survival. Thus, they will only adopt new technologies and social arrangements once they have been proven, not just hypothesized, to be beneficial. Thus, ventures in new branches of production that promise a profit are avoided, if a failure may threaten the survival of the farm. Within peasant communities, Scott found subsistence to be a “fundamental social right” that put a moral obligation on wealthy villagers to support the poor so their subsistence needs were met. Likewise, reciprocity is a central tenet of Southeast Asian peasant communities, meaning that favors and gifts are

expected to be returned, creating a sense of obligation to one another and the community.

In contrast to Scott, Paul Greenough (1983) argues that in Bengali, it is not the sense of scarcity and the threat of extinction that underlies the sense of subsistence and the moral economy, but abundance and indulgence. In a case study in Eastern Westphalia (Germany), an area characterized by industrial agriculture but rooted in a peasant cultural tradition, Baier et al. (2005) find that reciprocity is ingrained in local cultural norms. Labor at the farmstead and domestic level is expended at producing subsistence goods and services for collective consumption within the community through ways of gifting and exchange. This production outside the formal economy is a means to create sense of place, social cohesion, and social wealth within the community.

Sustainability is considered central to peasant ethics. Since the goal of the peasant economy is the reproduction of the farm as a source of livelihood for the farm family, the productive capital of the farm, such as soil fertility, genetic diversity, livestock health, and human labor need to be sustained for future generations. Sustainability is achieved through deep understanding and care for the local environment, features often associated with peasant farming. Peasants create and conserve agroecological knowledge through the intergenerational transfer of successful farming techniques and intimate observation of their immediate environment (Altieri 1988).

Drawing from case studies from around the world, Van der Ploeg (2008) identifies the peasant principle as a set of beliefs and embodied actions that typifies the peasantry, albeit moderated by local conditions. According to him, peasants are characterized through a strong sense of agency, autonomy, and hopefulness from which follow resistance and resilience. Van der Ploeg rejects representations of peasants as a passive group of people that merely responds to more powerful actors. Rather, peasants define and give meaning to their own actions and negotiate and adapt them vis-à-vis external pressures. Peasants’ daily work is directed toward increasing their autonomy to express and live their own cultural identity. Finally, the author points to a sense of hope and progress

that drives peasants to keep going against all odds; a belief, that “through hard work, cooperation, joint actions and/or overt struggles, progress might be wrought” (Van der Ploeg 2008, 274).

Social justice and cohesion is another value that is associated with many peasant communities. Although certainly not free of social stratification, many peasant communities try to mute inequality through a set of different cultural norms that mandate wealth to be redistributed (for example, through charitable donations) or shared (as commons or in extravagant festivities).

Ethical Questions Regarding the Peasantry

Acknowledging the existence of a peasantry, with its own values and objectives, poses important ethical questions for the development of society at large. The general thrust of global development policies, both capitalist and socialist, has been rather indifferent if not outright hostile to the interests of peasant farmers. The goal has been to modernize the peasantry so that it would fit into an idealized national economy. This provoked opposition among many peasants interested in preserving their culture and identities. Critical development theorists pointed out how the economic problems of peasant communities were not a result of their lack of ambition, but of colonialist exploitation and capitalist development policies.

Hence, the first ethical question is whether development should be evaluated by one universal theory (such as historical materialism or capitalist economic growth) or if there could be multiple paths of development, reflecting varying ideals among different communities. It is a problem for democratic participation and sovereignty if a development paradigm is imposed on a vulnerable population by more powerful actors with different interests. The second ethical question goes beyond that and asks, to what extent are peasant values and beliefs suitable guidelines for the development of societies at large? Some types of agrarianism offer a political philosophy that appreciates the ethics of peasant societies as such a model.

Going back to Chinese and European antiquity, agrarian ideals have reemerged throughout the history of political thought. Thomas Jefferson, for instance, saw independent farmers that worked their own land as a necessary condition for a functioning democracy. In Russia, Alexander Chayanov argued that the agricultural economy of the Soviet Union should be based on peasant farms and voluntary cooperatives instead of forced collectivization. Contemporary advocates such as Wendell Berry or Gene Logsdon highlight the importance of small-scale, sustainable farming, and local economies for human well-being.

Peasant Farming Today

Describing peasant farming today depends on the definitions of peasants being used. The difficulty of this task is further complicated by insufficient census data that usually do not reflect all variables that would be necessary to classify people as peasants by any of the aforementioned definitions (such as land ownership, market integration, or identity). Attempts to quantify the proportion of peasants in the world or in a given country are thus to be taken with caution. Often, numbers such as the global rural population, 3.3625 billion (46.4% of total population) in 2014, or employment in agriculture, 30.7% in the same year (FAO 2015), hardly do justice to the debates implied in the definitions of peasants. Regardless, peasant farming continues to be the livelihood strategy for many people in the world and an aspiration for even more. Eighty-four percent of the farms world-wide are assumed to be smallholdings on less than two hectares (Lowder et al. 2016). In Asia and Africa, these farms make up the majority of the agricultural operations, with most of them considered subsistence-oriented peasant farms. Beyond being a livelihood for the families on at least 475 million farms (ibid.), these farms provide food to other people in their communities as well. It has been estimated, that smallholder farms provide food to about 70% of the world population (ETC 2009).

The dominant development policies since the Second World War have confronted peasant

farmers with rapid change and challenges. In an attempt to integrate every country into the capitalist, global market, the World Bank, the International Monetary Fund, and powerful national development agencies such as USAID urged many of these farmers to abandon subsistence farming in favor of profit-oriented production. Although some farmers have used this strategy to improve their livelihoods, many others found themselves worse off. Farmers who could not compete against more productive operations, or farm workers whose labor had been replaced with machines or herbicides, became unable to subsist through farming and often had to migrate to urban centers in order to find work, leading to massive urbanization and slums where jobs were rare and underpaid and reliable social networks were not in place. Predominately men were the ones moving away to find work in the cities so that today women make up the majority of peasant growers.

Most often, the capability for farmers to decide whether they want to participate in commodity markets and global value chains is limited by the considerably greater power of large foreign corporations, development agencies, or philanthropic foundations that drive this process of market integration. Through a legacy of marginalization and dispossession, many farmers do not have another choice but to accept any opportunity to continue farming that is given to them, no matter the conditions. On the other hand, other farmers do not have the means to participate in commodity markets, such as sufficient acreage and output, which would make it worthwhile for any wholesaler to trade with them.

For farmers already integrated in the global market economy, neoliberal reforms in the last three decades imposed several “squeezes” on agriculture (Van der Ploeg 2008), that shifted farm production further away from subsistence needs to commodities. Jan Douwe van der Ploeg (2008) sets up a framework that helps us to think about peasant farming in today’s capitalistic market economy. For him, peasant farming is not an absolute category, but one of three organizing principles (the others being corporate and

entrepreneurial agriculture), between which farmers organize their production. Most farmers in developed countries produce commodities for sale to meet external requirements, such as financing land, machinery, seed, and fertilizer (that they no longer can procure outside the commodity market), and paying property taxes, as well as making a profit. At the same time, as time and means of production allow, many of these farmers work directly toward their own subsistence by producing foodstuffs for home consumption and trade within their community. Van der Ploeg (ibid.) describes this balancing between different modes of production as a struggle, in which many farmers try to shift the equilibrium toward the peasant mode of farming, attempting to increase their autonomy from commodity markets. Both in the Global South and North, peasant farmers increasingly turned toward pluriactivity, that is part-time, off-farm employment in order to make a financial income while at the same time holding on to their traditional livelihood.

Van der Ploeg (2008) makes a strong case that the peasantry does not just belong to the past and the present, but also to the future. He argues, that in many countries, the opportunities for rural people to work outside of agriculture are decreasing, as industrialization and rationalization continues to lay off growing parts of the industrial work force and other sectors fail to make up for this loss of jobs. He also finds that entrepreneurial farming failed to prove itself as a successful, sustainable, livelihood strategy. These trends make the peasant principle attractive for an increasing number of people. This process of *repeasantization* is evident in two trends: First, a growing number of urban people both in developing and developed countries are moving back to the land to start small, subsistence-oriented farms. Second, many existing farms align their production closer to the peasant principle than they did in the past decades.

Global Peasant Struggles

Peasants have long been involved in struggles; be it the struggle against an exploitive feudal

landlord, defending their land against an invading army, attempting to gain access to land, desiring to reorganize the rural social fabric, or implementing day-to-day labor to make a living on often marginal land. With the unfolding of capitalism across most parts of the globe, this list has been appended with strikes against low wholesale prices, the continuation of traditional farming techniques that have been outlawed by an increasingly controlling state and, more recently, the resistance against international trade agreements that are seen as threatening to the local economy. Prominent contemporary examples include the *Movimento dos Trabalhadores Sem Terra (MST)*'s struggle for land reform in Brazil, the Zapatista movement in Mexico, and the global organizing of La Via Campesina. Beyond these mass movements for land reform, landed farmers find other ways to resist exploitation and increase their autonomy. In response to increasing commodification, genetic modification and state regulation of seeds, an increasing number of farmers in different parts of the world organize to exchange seeds among each other with the goal to retain control over their genetic resources. The organic movement emerged out of a need of largely smallholder farmers in the Global North to maintain sustainable farming practices vis-à-vis an agroindustry that increasingly depended on artificial chemicals and fossil energy.

For Scott (1985), the most prevalent and effective tactics of peasant struggle are forms of "every day resistance" such as "foot-dragging, evasion, false compliance, pilfering, feigned ignorance, slander and sabotage" as opposed to overt revolt. According to Van der Ploeg (2008), the improvement of a farm's resource base through daily labor (improvement of the soil, care for animal health, maintenance of community ties) and investment in farm infrastructure makes up a central arena in the social struggle toward the emancipation of the peasantry, as are the continuation of traditional practices vis-à-vis pressures to modernize. The most prominent struggle that explicitly links the improvement of smallholders and farm workers with a peasant identity is the international struggle toward food sovereignty. The global coalition of peasant organizations La Via Campesina rallies

for change in the food sector so control over diets, production, and distribution of food shifts from corporations and financial institutions to the people through the strengthening of traditional farming practices and community-embedded social institutions.

Summary

Peasant farming is a major source of livelihood and provides significant amounts of food to the world population. Despite predictions that the peasantry would disappear with the spreading of capitalist relations of production, millions of farmers and farmworkers still identify as peasants, bridging class differences between farmers with land and other forms of capital and those without. While the majority of peasants live in developing countries, principles of peasant farming are a guideline for many farmers in industrial countries as well. The central principle is an orientation toward subsistence, that is the reproduction of the farm as a livelihood for the farm family. Despite vast cultural differences throughout the world, values that are commonly observed in peasant communities are a moral economy that is based on reciprocity and directed at social justice and cohesion, an aspiration to cultivate land sustainably so it remains productive for future generations and a desire for autonomy that keeps peasant farmers going under conditions of economic hardship and sometimes breaks out in covert or overt resistance. Today, large social movements such as the MST in Brazil or the international peasant coalition La Via Campesina organize around a shared peasant identity. The central ethical questions around peasant farming are to what extent it can, and should, coexist besides expansion-oriented forms of industrial agriculture, and whether it should be a role model for the development of society at large.

Permaculture

Todd Jared LeVasseur

Religious Studies Department and Environmental Studies Program, College of Charleston, Charleston, SC, USA

Synonyms

Alternative agriculture; Bottom-up global food praxis; Holistic food production; Multifunctional farming strategy; Permanent food production

Introduction

Permaculture is a design system where the goal is the generation and maintenance of resilient permanent cultures. These permanent cultures are based upon the sustainable production of permanent food supplies made possible by designing and managing nested systems of flora and fauna. The design aspect of permaculture is based upon insights drawn from holistic ecology, systems thinking, and sustainable agroecology. Permaculture is now a global movement but has its basis in the pioneering work of the Australians Bill Mollison and David Holmgren, who were inspired by agroecological forestry practices of the Southern Hemisphere as well as indigenous farming practices. Mollison explains that permaculture “claims to be designed agriculture, so that the species, composition, array and organization of plants and animals are the central factor” (Mollison 1979).

Permaculture design can be applied to any human habitat, from an apartment to a house, to an office space, to a farm, to a neighborhood street and community, to an entire town or even city. This is because the core features of permaculture design are transferable to any place humans live and work, because all such places are products of human design and intention. The goal of permaculture is to base such design on systems thinking so that the flourishing of human culture and human health can occur. While anthropocentric,

the underlying result is that if designed well, then nature also flourishes and is healthy, and the entire interrelated systems that make up permaculture communities are resilient, fecund, and able to generate abundance. At its core, permaculture aims to design efficient, healthy systems of permanent dwelling and habitat, at every scale, from a house to the planetary commons.

Key Permaculture Principles

Holmgren has created a list of 12 goals that guide the design, construction, and active maintenance of a permaculture system. The two key design principles are described here, but all 12 are seen as interrelated. The first principle is the recognition that all systems are nested and interconnected. The permaculture ideal is to design self-generating, closed-loop systems where energy cycles are captured and recycled within the system, leading to overall system growth, productivity, and health. This relates to a second permaculture principle, which is to observe and interact with the natural systems upon which a community depends for survival. By observing and interacting with systems, and especially food systems, permaculture design optimizes energy flow and designs for multi-function and for redundancies in food production systems. For example, a chicken provides multiple functions in a permaculture system: it provides nitrogen to the soil via manure; it provides eggs and eventually meat to humans; it provides insect control, thus helping eliminate the need for chemical-based pesticide inputs brought in from outside the system; it helps aerate roots via scratching; and it provides entertainment and natural beauty. With the use of a mobile chicken coop, a flock of chickens can quickly clear a field of weeds while also helping add nitrogen-rich manure to the soil. The field is then ready for polyculture planting, with each plant being part of a larger functional design. For example, plants are planted in “guilds,” so that they help provide synergistic support and nested function for one another. A blueberry bush might have nitrogen-fixing legumes planted under it, while beneficial

flowers might be planted around it that can attract pollinating insects, and after they fall the leaves of the bush becomes part of a compost pile so that nutrients are able to be applied back into the system. Designing for redundancies means that along with chickens, a system may also include ducks, geese, or turkeys; and besides blueberries, a system may also contain bramble bushes or other fruit-bearing bushes. These two principles – observing and solving for pattern and system efficiencies and designing for function and redundancy – form the basis of permaculture design for any system and especially for agroecosystems that provide humans with food, fuel, and fiber.

Another core permaculture design principle is designing systems so they can catch and store energy. This may include using south-facing walls to capture radiant heat, using solar energy for power and to heat water, harvesting rain water, and building swales and hedgerows. Another principle is based upon understanding a permaculture system as being a closed system, so that the goal is to produce no waste, especially toxic waste. In a closed system, the waste of one process becomes the energy to create another process. Compost is the ideal example of this aspect of permaculture design.

A further principle is to create edge and zone habitats where creativity can occur. Related to the principle of observing patterns in nature, permaculture design recognizes that zone/edge ecosystems in nature are the most creative; for example, coral reefs, estuaries, and wetlands contain very high levels of biodiversity and nutrient cycling. This relates to designing by zones, with zones closest to a house or common area containing flora and fauna that are used the most and that need the most attention, such as greens and culinary spices. The further out from this zone, typically called zone one, then the design changes, so the farthest zone, typically called zone five (most permaculture systems at the farm or community level contain five zones), contains sustainable timber production. The ideal goal of permaculture in terms of food production is to create edible forests that are populated by stone fruits and nut trees. These are long lasting and resilient and provide multiple functions. In tropical and

subtropical areas, they also provide a year-round supply of calories, and they create habitat for other species. These and other principles help permaculture designers work towards achieving their goal, which is to capture sunlight energy and cycle this through closed-loop design systems based on nature's patterns where the continual output is increased yield of food items and the sustainable use of natural capital.

Permaculture Ethics

While permaculture aims to design sustainable, resilient permanent cultures that are built upon perennial food production, there is also a very clear ethical element permeating permaculture. This ethic is based upon mixing insights gleaned from ecology, sustainability, sustainable agriculture, environmental philosophy, traditional ecological knowledge, and Marxist political economy, with other intellectual tributaries adding to the overall ethical milieu of permaculture. The result of this ethical component is that many in the global permaculture movement are critical of industrial agriculture and the industrial economy and they are concerned with issues like excessive human population growth, species extinction and loss of biodiversity, and loss of indigenous cultures. The ethic is formulated as “Care for the Earth, Care for People, and Fair Share.” It may also be expressed as “Earth Care, People Care, Fair Share.” This ethical mantra recognizes that the earth is a finite system, and everything needed to survive is generated from sunlight entering our earth's system. Thus, basing a permaculture design on these ethics works to ensure that the earth, from which everything else derives, is healthy, and at the same time, everyone in a community (from local to global) is cared for and has access to healthy food and adequate resources because they are equitably shared. By designing edible landscapes of polyculture guilds, multi-functional flora and fauna, and by farming and growing these in ways that minimize inputs of chemical fertilizers and pesticides and that instead promote system resilience, permaculture aims to generate food security.

Summary

Permaculture has gained in popularity in the last 10 years, with a proliferation of blogs, magazines, and workshops devoted to teaching permaculture design and principles. There has also been a proliferation of online websites devoted to permaculture and online videos that teach permaculture techniques. There is a loosely affiliated global permaculture network that hosts trainings in permaculture design and a residential training typically lasts 1–2 weeks. People pay to attend these trainings and receive a certification in permaculture design. They are then able to offer trainings to other people interested in learning about permaculture. Permaculture has guilds, organizations, training centers, and networks in most every country. The Transition Town movement has grown out of permaculture, and there are many intentional-based communities and ecovillages based upon permaculture design and ethics, including Crystal Waters in Australia, which was founded by Mollison and Holmgren. The goal of all of these trainings, groups, teachers, and communities is to create resilient, permanent human cultures built upon the ethical foundations of permaculture.

Pest Control

Introduction

Pest control is the human-directed effort to reduce the population and impact of any species that harms agricultural production and food storage. A pest species can be arthropod (insect and mite), vertebrate (animal), plant (weed), or plant pathogen. A control strategy may be chemical, mechanical, or biological. A chemical control is the spraying of a pesticide. Mechanical control consists of some kind of physical disturbance of the pest species or its habitat (e.g., plowing weeds or removing all crop residues which provide refuge for insect pests). Biological control is the manipulation of beneficial organisms to reduce the impact of pest species. This entry chiefly addresses arthropod (insect and mite) pests in agriculture and insecticides and their alternatives in crop production.

Pest control emerged as an ethical issue with industrialization of agriculture and the associated development of pesticide technologies. Health and environmental problems were popularized by publication of Rachel Carson's (1962) *Silent Spring*, which takes its title from the collapse of bird populations due to pesticide poisoning. *Silent Spring* was the first major book to raise serious questions about the industrialization of agriculture. Carson's argument brought invisible agrochemicals into public view, documenting how pesticides used to produce food were also poisoning human health and the environment. There are thousands of pesticide products using many different biological mechanisms to kill or control different kinds of pests, rendering categorical statements about the harm or safety of pesticides meaningless. Some classes of pesticides pose grave risks to human health, but those risks vary widely by pesticide, type and duration of exposure, and prior health condition. Pesticides contaminate surface and groundwaters. Organisms that depend upon freshwater ecosystems are particularly vulnerable to pesticide contamination: fish, mammals, and aquatic invertebrates.

Carson made normative claims upon society and its institutions on the basis of ecological principles, arguing that many pesticides should be banned and that ecologically rational alternatives to pesticides exist and should be used. She

criticized the atomistic and anthropocentric worldview that gave rise to indiscriminate pesticide use, and its assumption that human beings could and should master nature. Her work led to the creation of the US Environmental Protection Agency and the banning of some classes of harmful pesticides. *Silent Spring* is the most influential book in this topical field and laid down fundamental ethical arguments in pest control that continue to be debated today.

Pesticides are powerful technologies, yet they are very simple to use. The propensity of pesticides to cause undesired negative consequences on people and the environment has made them the most controversial agricultural technology – until transgenic crops were developed. Pesticides persist as an ethical problem because they are an economically rational but ecologically irrational technology, with direct economic benefits accrued by the private user yet many diffuse negative impacts on human health and public goods that are difficult to economically quantify. Their continued use reflects the broader pattern of utilitarian thinking in industrial agriculture (Thompson 1995). This ethical problem connects activities in fields, factories, homes, and government.

Scientists have demonstrated that ecologically informed alternatives exist or could be developed to take the place of pesticides; however, these require additional labor to assess the actual threat posed by pests. Although slow to be realized and fitful, some progress in the voluntary reduction of harmful pesticides has been made, from the development of less hazardous chemicals to the greater use of integrated pest management strategies (see below). Were the full range of off-site negative impacts of pesticides charged to farmers, their economic calculus would shift and more reductions in use could be achieved. However, the use of pesticides in aggregate does reduce the cost of food to consumers. This essay begins with an overview of pests and the pesticide complex, followed by discussions of the human health and environmental impacts of pesticides. Ecological and political controversies surrounding pesticides are then presented, followed by a discussion of more sustainable alternatives.

Pests and Pesticides in Agriculture

A tiny fraction of the world's arthropod, plant, and plant pathogen species damage and destroy agricultural crops, although estimating the economic cost of pests is notoriously difficult. Worldwide, approximately three billion kilograms of pesticides are applied annually, worth US \$40 billion. Data on US pesticide use and costs is strongest and illustrates the economic calculus. Roughly one sixth of the global total is applied in the USA (Pimentel 2005). The majority of US pesticides are herbicides used to control weeds in annual crops, but most insecticides are applied to horticultural and perennial crops. There is roughly a four-to-one economic return to the agricultural producer on pesticide costs. Despite significant pesticide use, US agriculture loses up to 37% of its yield due to pests, roughly a third attributable to arthropod, plant, and plant pathogens (Pimentel 2005). Many of these pests are indigenous to the region of a crop's center of evolutionary origin and have found their way to new crop production regions. Other pest species have moved over from related host plants to attack introduced agricultural crops.

The global pesticide complex consists of all aspects of pesticides' lifecycles, from conception to human and environmental fate (Galt 2008). This complex is extraordinarily complicated, and data to accurately characterize it is thin and uneven. Across the developing world, data is scarce if it exists at all. A tiny fraction of applied pesticides makes physical contact with intended target pests. Research has found that between 0.001% and 0.3% of the amount sprayed reaches pests (Pimentel 1995). The human and environmental fate of the other 99 + % of pesticides dominates the ethical debates about pest control. Pesticides break down into their chemical components in the environment and thus become less hazardous. Pesticides developed in the post-World War II era were highly persistent, causing environmental harm over years or decades. When these were banned by governments, some of the pesticides that took their place were more acutely hazardous, but much less persistent. Over the past generation in the developed world, new pesticides have been developed that are less hazardous and

affect a smaller subset of insects. Some progress has been made in developing alternative delivery technologies, but these have generally been in a few high value crops.

Human Health Impacts

Ethical consequences of pesticide use may be roughly divided into human and environmental impacts. Some social groups are at much greater risk of exposure to pesticides and their negative effects than others. Those most at risk are those who handle and apply pesticides regularly, followed by farmers and farmworkers, their families, rural communities, and consumers. Estimates of pesticide poisonings range between one and five million every year worldwide (Harrison 2011). Those who mix, handle, and apply are routinely exposed to hazardous materials. Many farmworkers who prepare and apply pesticides are unable to understand the full risks of handling or mishandling pesticides (Wright 1990). Protective gear is mandated by government regulation in industrialized countries, but in the developing world, many pesticide applicators do not use this. Farmers and farmworkers who do not apply pesticides may be exposed to them by drift or direct contact on crops. Government regulation in industrialized countries restricts the access of workers to recently sprayed fields until they are assumed to have broken down chemically.

Families of farmworkers are exposed when their parents return home with clothes contaminated by chemical residues. Children's health is more vulnerable to pesticides due to their biological development processes. Rural communities are disproportionately exposed to pesticides due to their proximity to farms. Pesticide residues have been found on some fresh produce, even though this is regulated. In developed countries pesticide residues in produce are generally very low and generally considered to pose trivial health threats, although studies have shown that residue testing of imported produce may be inadequate (Galt 2009). Activist critics of pesticides have appealed to consumer anxieties about pesticide residue.

The global pesticide complex is now highly differentiated, reflecting the broad trends in economic globalization (Galt 2008). Industrialized countries began regulating, restricting, and banning pesticides in the 1970s; however, many of the pesticide-manufacturing companies operate in many countries. After they were banned in Europe and North America, hazardous pesticides continued to be manufactured there, but were exported to developing world farmers, where regulations were weak or nonexistent. Some of these pesticides were subsequently found on produce imported back to countries where they were banned, a phenomenon popularized as the “Circle of Poison” (Weir and Schapiro 1981). This popular conceptualization has persisted, despite scholarly criticism of it as overly simplistic and inaccurate (Galt 2008). Wright (1990) demonstrated that public concern about pesticide residues prompted growers in Mexico to replace persistent pesticides with acutely toxic chemicals, decreasing the risk of pesticides making their way into the USA on food, but increasing the health risks to farmworkers. Thus, consumer concern about pesticides had the perverse effect of exposing politically vulnerable farmworkers to more dangerous farming practices. Wright’s work illustrates the critical dynamic of power and knowledge in efforts to reduce pesticide impacts. Subsequent pesticide manufacturing has shifted to the developing world, and a divergence of pesticide use depending upon whether the product will be exported for the regulated international market, or marketed domestically with little if any regulation (Galt 2009).

Pesticide drift is the airborne movement of pesticides into residential areas. Drift is invisible, often odorless, and ephemeral (Harrison 2011). It can result in severe injury or even death. The normal application of pesticides routinely results in drift that may travel meters or many kilometers and thus contact human beings, other living organisms, other crops, soil, or water. Pesticides may be carried far by winds or in fog. Drift incidents are characterized by many pesticide companies and regulatory agencies as “accidents,” suggesting that they could not be anticipated and no one is responsible for them. Critics describe

drift as routine, an anticipatable consequence of pesticide use, and accuse regulatory agencies of disregarding patterns of negative health consequences on workers and communities. Poor, rural communities are at the greatest risk of pesticide drift, rendering this an environmental justice issue. Anti-drift activism appears to be on the rise (Harrison 2011).

Contact with some classes of pesticides poses dangers to human health. Some pesticides can cause direct injury (e.g., harm to lungs or skin), systemic health problems (e.g., harm to endocrine, or immune systems), cancer, or in some cases, death. These symptoms may be immediate or slow to develop. Mothers exposed to low doses of some pesticides can pass chemicals to children in utero and thus cause substantial harm to the child’s neurological system, with lifelong health implications. There are substantial epistemological challenges to proving scientifically that a specific pesticide exposure event (whether in the field, from drift, or residue on produce) resulted in a human health consequence. Toxicological investigations of pesticides are frustrated by the diversity of biological mechanisms of different classes of pesticides, the different means and duration of exposure, the accumulation of harmful chemicals from many sources over a lifetime, the complexity of human bodily responses to synthetic chemicals, and the interaction of all of these factors.

The Ecological Dimension

Pest control was revolutionized by the discovery and use of DDT, a synthetic compound that became widely used during World War II (Perkins 1982). Prior to DDT, insecticides had been less effective and were costly relative to the control they provided. DDT is a broad spectrum contact insecticide, meaning that it kills most kinds of insects upon exposure, often immediately. It was initially believed to be safe to use on human beings and provided substantial benefits during the war by killing lice on human refugees and mosquitos bearing diseases, especially malaria. The discovery of DDT launched the

production of a class of insecticides with similar attributes that became widely used for decades. DDT was also used in mass outdoor spraying campaigns to control mosquitos in many countries.

The rapid adoption of these insecticides in the postwar years profoundly shaped the pest control practices, the farming practices more generally, the science of entomology, and the agrochemical industry (Perkins 1982). Older, less effective and more harmful pesticides were virtually abandoned. Research into and practice of mechanical biological control entered a period of decline. Farmers who quickly adopted these techniques gained economic advantage over their neighbors. Insecticides dominated research in entomology, and fueled a dramatic expansion of the farm chemical input industry. The economic advantage of these insecticides substantially accounts for this, but persistent pesticide use also reflects a broader social attitude of faith in technological progress that discourages critical questions about undesirable consequences (Perkins 1982).

Carson brought to public attention the ecological principles that made indiscriminate use of insecticides self-defeating. The DDT family of insecticides initially killed all insects, including natural enemies (beneficial insects such as predators and parasitoids that would naturally suppress pests). Their lethal action was generally immediate and impressive to observe. However, populations of plant-eating insects generally recover more quickly from insecticide treatment than beneficial insects, which are generally more vulnerable to pesticides. No longer held in check by natural enemies, insect pest populations may be higher several weeks after pesticide treatment than before. This phenomenon is termed a pest outbreak. Pesticide resistance is the ability of a population of pests to survive pesticide treatments that had previously controlled that population. Resistance develops in a population through a natural selection process that favors the reproduction of organisms that are less susceptible to the specific lethal effect of the pesticide, and these are able to pass on their genetic traits to their offspring. Resistance causes pesticides to fail. More than 500 pest species have populations that

manifest resistance. In an attempt to compensate for these problems, farmers may use even more pesticides, thus paying more for less benefit, and accelerating the process of resistance, a process known as the pesticide treadmill (van den Bosch 1978).

Carson's *Silent Spring* is one of the most influential expressions of environmental philosophy ever published, due to the topic, her evocative language using powerful imagery, and her broader critique of science and government. She described in scientific and poetic terms how new insecticides were pushing popular bird species (e.g., bald eagle, brown pelican) to the brink of extinction. Using normative language, she drew attention to the irreversibility of species extinction. Carson raised philosophical questions about human thinking about new technologies. She criticized the indiscriminate use of pesticides, but also the broader scientific paradigm that promoted them. She decried the seeming inability of pesticide users to recognize its serious environmental consequences and called for more investment in biologically based alternative pest control techniques. She also raised broader questions about scientists and politicians and their paradigm (or institutional patterns of thought), asking why they disregarded widespread problems caused by indiscriminate use of insecticides.

Political Controversies

Silent Spring prompted a nationwide debate in the USA about pesticides, technological progress, environment, and regulation. Carson's testimony before the US Congress made several normative claims about pesticide use, regulation, and policy, and these were carried forward by advocacy groups and in lawsuits over subsequent decades. She argued individuals should have a right to protection from poisons introduced by others into the environment; only those able to understand the hazards of pesticides should be allowed to purchase and use them; regulatory institutions should be independent of political influence and safeguard public health and the environment; the government should fully support the development

of safe, ecologically based alternatives. Carson criticized the US Department of Agriculture for its failure to question the indiscriminate use of pesticides and to investigate the health and environmental consequences. Critics dismissed Carson as a hysterical woman lacking scientific credentials and accused her of ignoring the benefits of pesticides in the control of insect-borne disease. So powerful was Carson's work that it provoked immediate public pressure on elected officials for greater environmental protection. It galvanized civil society groups who brought new ideas about the environment and scored legal and legislative victories by linking popular ideas in society with political advocacy. The US Congress created the US Environmental Protection Agency (EPA). To address charges that the US Department of Agriculture suffered from a pro-pesticide bias, the congress passed the Federal Environmental Pesticides Control Act in 1972 to transfer responsibility for pesticide registration and regulation to the EPA. The move to ban DDT began in some European countries in the 1960s, and a high profile lawsuit led to a ban on DDT in the USA in 1972. Carson's critique was picked up in many countries, prompting pesticide restrictions and the creation of environmental agencies.

Despite Carson's influence on public opinion, pesticide use continued to rise over subsequent decades. To carry forward *Silent Spring's* critique, entomologist Robert van den Bosch wrote *The Pesticide Conspiracy* (1978), charging the entire pesticide research, manufacture, sales, and use system of suffering from a conflict of interest. He described a "pesticide mafia" of agrochemical manufacturing companies, university and public officials, and large growers who found it to their personal financial interest to promote pesticides in violation of the public interest. He railed against their collusion and claimed that they purposefully sabotaged alternative research and strategies, subsequently labeled as van den Bosch's "corruption" hypothesis (Perkins 1982). Activist criticism of pesticides has fostered anti-farming attitudes among the public. Subsequently, much of the energy of antipesticide activism has shifted to contest transgenic crops, extending analogous ethical criticisms to that technology.

DDT and associated products were banned worldwide as an agricultural pesticide by the 2004 Stockholm convention, although it is still used in farming in some countries. In 1996, the US Congress passed the Food Quality Protection Act, the most significant reform of the nation's pesticide laws since the creation of the EPA. It mandated a major, thorough analysis of pesticides, including those previously exempted from review, informed by risk analysis, and improved understanding of medical toxicology and the role of cumulative health impacts. After *Silent Spring*, pesticide use in the USA continued to rise, although chiefly through greater use of herbicides in corn and annual crops, and has remained relatively stable over the past generation. The intent of the Food Quality Protection Act – and others like it in the EU and elsewhere – was to favor "softer" (less hazardous) pesticides, and some progress has been made. Manufacturers have developed pesticides that are more selective and less persistent; products that attract pests into trap to kill them, thus precluding the need for spraying and synthetic insect pheromones which interfere with insect reproduction (Warner 2007).

In the USA, farmers use roughly \$10 billion in pesticides annually, and this provides approximately \$40 billion in the value of crop protection. However, Pimentel (2005) estimates that they result in approximately \$9 billion in harm on public health and the environment. Thus, those who profit the most from the production, sale, and use of pesticides receive almost all the economic benefit, and the costs are imposed on other people and the environment. This uneven distribution of costs and benefits underpins the ethical assertions that public funding of alternatives to pesticides is a matter of justice (Pimentel 2005).

Scientists and policymakers have long recognized that some introduced (nonnative) species can become highly destructive pests. To detect and exclude them, public authorities regulate international trade and inspect imported goods, especially fresh produce. If new potential pests are detected, imported goods are destroyed or turned away, a practice known as agricultural quarantine. If introduced pests become established, they may require

ongoing control, often with pesticides. Eradication is the effective removal of all pests in a new region to prevent recurring costs associated with control. Eradication of introduced pests becomes highly controversial when pests establish in residential or urban landscapes, because this requires the application of pesticides in areas where nonfarming regions for the benefit of agriculture. Eradication is costly and rarely successful, but when it does succeed, the aggregate economic benefit is substantial.

The Search for Alternatives

Biological control is the action of natural enemies in maintaining a pest's density at a lower average than would occur in their absence. As a pest control strategy, classical biological control is the importation and introduction of natural enemies to control pests, generally introduced arthropods and weeds. Biological control entered the popular imagination in the late nineteenth century with the successful control of a nonnative California citrus pest, the cottony cushiony scale. An American entomologist in Australia discovered that the vedalia beetle, a natural enemy, effectively controlled the scale in its native habitat. He shipped beetles to the USA to be released in citrus orchards, and they quickly reproduced and provided control of the pest (Perkins 1982). When successful, classical biological control is an ideal pest control strategy because the introduced natural enemy population provided recurring suppression of pests. Classical biological control is a public interest science because its beneficiaries are farmers and society as a whole, but it depends upon the ongoing investment of public funds. Biological control was virtually abandoned as a science in the DDT era, but enjoyed a surge in interest after an endorsement by Carson (Warner 2007).

However, in the 1950s, a band of entrepreneurial entomologists in California developed a framework for controlling pests now known as Integrated Pest Management (IPM). Originally developed with insect pests, IPM has subsequently been expanded to include all pests, including weeds, vertebrates, and pathogens.

The scientists who pioneered IPM did so to help growers make pesticide use more pragmatic, but subsequently appealed for its adoption to serve the public interest (Perkins 1982). IPM built upon the ecological principles in biological control (e.g., predator-prey relationships, population dynamics, and habitat manipulation) to recommend pesticides only when pest populations rise beyond an economic threshold at which the cost of the pesticide will be exceeded by pest damage. Its developers used the term "integrated" because they recognized that biological control alone as a strategy was not necessarily economically practical, but that when integrated with other techniques, it can be. IPM assumes an understanding of the ecological relationships between crop, pest, natural enemies, and human decision making. IPM recommends pesticides but only in ecologically informed ways.

The rise of ecologically informed alternative agricultural paradigms poses a challenge to continued reliance on manufactured pesticides. Organic agriculture, when true to its ideals, follows an alternative farming philosophy and uses alternative farming practices. Organic farming practices pest control. It uses certain forms of pesticides that are less hazardous and derived from naturally occurring substances. Experienced organic farmers frequently report they have few problems with insect pests, but that weeds are difficult to control with organic techniques.

Agroecology is defined as the application of ecological concepts and principles to the design and management of sustainable food systems (Gliessman 1998). Thus, it seeks to mimic the function and structure of "natural" ecosystems, by enhancing nutrient cycles, natural pest control, and the biodiversity of farming systems (Warner 2007). Agroecologists criticize reliance on monoculture because this production system causes pest outbreaks and relies upon agrochemical inputs to remain productive. Monoculture generally increases per acre production of one crop, but the resulting farming system is inherently brittle and unstable. The logic of monoculture generally precludes serious consideration of farming systems that mimic natural ecosystems.

Summary

Pest control is a foundational component of industrial farming. A tiny fraction of the world's arthropod, plant, and plant pathogen species damage and destroy agricultural crops, but their economic impact is considerable. The rapid adoption of DDT-related insecticides after World War II profoundly shaped the pest control practices, the farming practices more generally, the science of entomology, and the agrochemical industry. Although controversial and contested, pesticide use is driven by the economic advantage it provides to the users, even though substantial (but difficult to measure) costs are imposed on workers, rural communities, and the environment.

Rachel Carson's *Silent Spring* made agricultural pollution – and pesticides specifically – visible to society by decrying its widespread impact on wildlife. *Silent Spring* is among one of the most influential expressions of environmental philosophy ever published, due to the topic, her evocative language using powerful imagery, and her broader critique of the paradigm and human values that gave rise to the pesticide industry. She brought to public attention a most disturbing irony: the agriculture upon which human society depends for sustenance was poisoning the environment and human beings. Indiscriminate use of chemical technologies risked the planet and future generations. Carson pointed to “extraordinary array of alternatives,” based on ecological science. “Much of the necessary knowledge (of alternatives) is now available but we do not use it” (Carson 1962, p. 11).

Introduction

The Food and Agriculture Organization of the United Nations (FAO) and the World Health Organization (WHO) define a pesticide as “any substance, or mixture of substances of chemical or biological ingredients intended for repelling, destroying or controlling any pest, or regulating plant growth.” Of course this definition of a pesticide requires a further definition of the term pest, which FAO/WHO defines as “any species, strain or biotype of plant, animal or pathogenic agent injurious to plants and plant products, materials or environments and includes vectors of parasites or pathogens of human and animal disease and animals causing public health nuisance” (FAO and WHO 2014). Pesticides are used broadly around the world to enhance agricultural production, to protect human health, and to play a variety of roles in preserving materials or environments important to human beings. Global pesticide usage totaled 5.8 billion tons in 2012. At that time, 90% of the pesticides used in the United States were used to support agriculture (Atwood and Paisley-Jones 2017). It’s likely that other countries reflect a similar or greater ratio of agricultural use to nonagricultural use of pesticides. Pesticides are biologically active by definition and as a result pose a risk of harm to humans and the environment. The importance of these materials in agriculture, the potential for harm, and the amount of pesticide distributed in the environment suggest that pesticide use is a fertile area for ethical thought. The focus of this essay will be the use of pesticides in agriculture in concert with the theme of the encyclopedia, though pesticides have important uses in other sectors, such as public health.

The ethics of pesticide use may be considered from a variety of perspectives. The effect of a single pesticide on human health in the context of agricultural benefit is an immediately apparent ethical issue. Similarly, the effect of a pesticide on the environment or elements of the environment has ethical implications. Depending on ethical commitments, we may consider the effect of pesticides on individual organisms, including the pest. Much of the conversation about pesticides

focuses on the risk of harm resulting from pesticide use. How risks are calculated and how they are applied to decision-making should integrate both the reasoning of science and ethics. Assessment of risks is an important part of the regulatory process in which pesticides may be approved or limited in their use. The communication of risk to the public requires a determination of educational need, transparency, and the extent of information to be shared. Considering the topic more broadly, it has been suggested that pesticides enable what is termed industrial or extractive agriculture. To what degree is the use of pesticides entangled with industrial agriculture? And, are there other methods of controlling pests that can reduce or eliminate pesticide use? Continued human population growth projected through the end of the century indicates the potential for food scarcity. Proponents of pesticide use feel that pesticides are necessary to use cultivated land most efficiently to provide the highest yields. But, some uses of pesticides in agriculture may be cosmetic, rather than to increase production. There may also be important questions of equity when organic produce, available at a higher price, forces a choice for lower-income consumers between non-pesticide-treated produce and pesticide-treated produce available at a lower price.

Human Health Effects

Pesticides may affect human beings through dermal and inhalation exposure in the application process, through drinking contaminated water, and through the ingestion of residues on produce. Pesticide effects may be acute, causing symptoms within hours or days. Or, pesticide effect may be chronic, manifesting over a period of months to years. Pesticide manufacturers conduct laboratory studies with animals to establish the acute and chronic toxicity of pesticides through the variety of routes of exposure. The data they generate supports the development of use instructions and cautionary information on the pesticide label and the product registration process. Data from other species is extrapolated to human beings to determine safe exposure levels by all

routes. Recently, though, we have learned that younger children are more susceptible to pesticide effects than adults, resulting from physiological and behavioral differences. Pesticide exposure increases the risk of childhood cancer and affects neurological development. Children in agricultural areas may be exposed to pesticides through spray drift or exposure to parent work clothes or transfer to the child's environment from a worker's shoes. Are there situations in which some of these harms are acceptable?

Different ethical approaches may treat pesticide-related human health effects in divergent ways. It is possible that a consequentialist approach might allow harm on balance, if it results in saving more lives from starvation than the number of lives affected by pesticide-related illness, for example. But there are multiple consequentialist approaches, some of which would find these health effects unacceptable. Proponents of deontology would likely reject harm to an individual, respecting that person's autonomy, despite potential gains in yield that might lower prices or feed more people. Another approach is to consider the inequality of opportunity (Daniels 2010) generated by pesticide-related illness. In this account, justice obliges us to safeguard people's normal opportunity by decreasing the risk of pesticide-related illness. This way of conceptualizing justice and pesticide illness is useful in identifying equity issues in pesticide exposure. For example, farm workers as a group are at a higher risk of pesticide exposure than others in our society. It seems clear, given a higher potential for pesticide-caused illness, that they do not have fair equality of opportunity. The greater sensitivity of children to pesticides suggests that they also do not have fair equality of opportunity as a result of pesticide use. Only a small proportion of children may be exposed to pesticides, but their greater sensitivity means that more will be affected than adults.

Generally, human illness resulting from pesticide exposure places obligations on those who manufacture, regulate, and apply pesticides. Pesticide manufacturers have an obligation to develop pesticides that have the least possible impact on human beings. Further, manufacturers must take steps that insure that pesticides are

applied in a manner that reduces exposure throughout the chain of production, from factory to farm workers and through consumers. Manufacturers must identify appropriate means of protecting people that are working in fields that have been treated with their product and should work with growers to insure that the precautions are followed. This includes methods of applying pesticides that reduce pesticide drift into non-agricultural areas. Farmworkers should be educated on the risk of bringing pesticides home from the fields, and manufacturers and growers should develop practices that prevent contaminated clothing and shoes from carrying pesticides out of the field. Manufacturers should continue to improve labeling to achieve the understanding of risks and handling precautions for pesticides – particularly in developing countries where pesticide misuse issues are greatest. Manufacturers need also to consider how growers and consumers can better remove pesticides from produce. This may entail pesticide design, formulation, and communication of best pesticide removal practices to growers and consumers. Manufacturers and growers must work together to insure that the lowest possible level of pesticide residue is achieved on produce. To this end, growers and manufacturers have a responsibility to use means that reduce the amount of pesticide applied to the lowest amount possible. The reduction of pesticide use entails the elimination of misuse, overuse, and unnecessary use of pesticides, as well as use of techniques that encourage non-pesticide pest reduction.

Moral Standing of the Pest

Pesticides in agriculture include rodenticides, insecticides, miticides, herbicides, fungicides, bactericides, and virucides. Ethical treatment of the different levels of biological organization of these pest organisms varies among philosophers. Sentience, or the ability to suffer, is a particularly important consideration for a consequentialist approach to ethics and to determining which organisms have moral standing. Discerning interests and intrinsic value is important to a

deontological approach. A capability approach emphasizes what organisms are able to do and the life they can achieve. For purposes of this entry, rather than arguing whether any of these organisms deserve moral consideration, the case that an organism does have moral standing will be considered.

The concern for the welfare of pest organisms must be seen in the context of the human right to adequate food and the right of humans or other organisms to defend themselves against organisms that threaten them. When a pest organism stands between humans and sufficient food, then a means of protecting human food, including pesticides, is warranted. But, given a pest's moral standing, a grower must make efforts to minimize the impact on pest populations. This objective may be achieved in some cropping systems by establishing an economic threshold for the use of pesticides. Pesticides are not used then until pest populations reach a threshold that is proven to have an economic impact on yields (variations in the approach are necessitated by kind of pest, e.g., fungi versus insects). The use of pesticides to produce cosmetically perfect fruit and vegetables is not warranted if a pest has moral standing. In this case, the appearance of fruit doesn't contribute to a human need. The food value of an imperfect fruit or vegetable is the same as that of a perfect fruit. The use of pesticides also may not be warranted in non-food production if a pest is determined to have moral standing. The production of crops used for biofuels may not warrant the protection of pesticides, for example. The production of biofuels is controversial both in terms of arable land lost to food production and in questioning the true contribution to greening the energy supply. If biofuel crops do not fulfill a legitimate human need, then pesticide use against a pest with moral standing is not warranted. A similar position could be taken against the use of pesticide in the production of flowers if pest organisms are judged to have moral standing. In this last case, there are broader implications to consider. Much of the world's floriculture occurs in developing countries, where it can be an important source of employment. Importing countries require that flowers

are free of pests. Use of pesticides is necessary to produce pest-free flowers and maintain an important source of developing country employment. In this case, it may be permissible to use pesticides against a pest with moral standing since floriculture workers could lose employment that supports them and their families.

Nontarget Effects

Pesticides are generally aimed at a certain pest or complex of pests, but they are not discriminating in their effect. Other nontarget organisms that contact the pesticide may also be sickened or killed. Again, depending on the ethical approach, these organisms may have moral standing. If so, as collateral damage suffered to maintain crop yield, they must be considered in the same way as the pests described above. Additionally, to avoid harming nontarget organisms, manufacturers should endeavor to produce pesticides that are narrowly targeted at pest species.

Leaving aside the question of the effect of pesticides on individual organisms, nontarget effects may be construed more broadly as environmental effects. Pesticides have numerous effects in the environment. Examples include the effects of pesticides on predators, soil organisms, pollinators, aquatic organisms, and plants. Predators of insects or other organisms contaminated by pesticide may accumulate pesticide in their organs or fatty tissue. The pesticides may then become biomagnified as they move up the food chain to higher-order predators. The more concentrated pesticides then pose a greater health risk to these upper food chain predators. Sickening or killing higher-level predators has effects that may reverberate throughout the ecosystem. Top predators can be keystone species that maintain an ecosystem. Without them, an ecosystem may be drastically changed.

Soil organisms such as earthworms, millipedes, fungi, and bacteria may be affected by the use of pesticides. These organisms are responsible for decomposing organic matter and maintaining soil fertility. The loss or reduction of these organisms may cause the need for soil amendments.

The pesticides that find their way into the soil may also be carried by runoff or through infiltration of the soil into groundwater, streams, ponds, rivers, and lakes. Pesticide drift may also carry pesticides into water bodies. Pesticides like the pyrethroids are highly toxic to aquatic life, affecting the structure of the aquatic ecosystem. Herbicides affect not just weeds but other plants that grow in and around the crop plants. The nontarget plants support communities of herbivores, particularly insects and mites, which may not feed on the crop plant. So losing the nontarget plants may also cause the loss of some of the herbivores if they can't find alternative food sources. The nontarget plants may also support pollinators generally and especially at times when the crop plant isn't flowering. Loss of the nontarget plants may mean loss of native pollinators. Insecticides also directly affect pollinators as seen most recently with the effect of neonicotinoids on bees. Neonicotinoids are very toxic to bees, but sublethal doses of neonicotinoids can also be important, affecting bee foraging and learning.

Each of the nontarget effects mentioned impacts the biodiversity of the ecosystem encompassing the agricultural land. It is argued that biodiversity itself has value and should be respected (United Nations 1992). Biodiversity is a way of expressing the number of species found in a particular habitat or ecosystem, and species too may be thought of having value (Rolston III 2012). Consideration of the ethical value of biodiversity and species must impact decision-making by manufacturers, farmers, and regulators on pesticide use. The US Environmental Protection Agency (EPA) has found that the pesticides chlorpyrifos and malathion likely adversely affect 97% of the endangered and threatened species in the United States (Environmental Protection Agency 2017). These assessments by the EPA involved all uses of the insecticides – not just agricultural. But, it is clear that if we value species and biodiversity, pesticide use must be reduced, and pesticides must be applied in a very controlled manner that decreases release into the broader environment.

The potential for harm to endangered species speaks to broader effects of pesticides on the

ecosystem. The effect of the loss of keystone species on the ecosystem was mentioned above. The loss of flowering plants that support pollinators and the loss of the pollinators themselves impoverish an ecosystem. An ecosystem can often absorb the loss of a few species, but loss of a critical species can affect other species all along the food chain. Reduced pesticide use and controlled application by the farmer will help. But, the pesticide manufacturer needs to continue to make efforts to find more environmentally friendly products. Environmentally friendly products might include rapid breakdown into innocuous by-products, a mode of action that is targeted as narrowly as possible toward the pest organism, and limited mobility in the environment – limited potential for transport through soil or in water.

Regulation

The development of increasingly sophisticated pesticides has been followed by the development of a governmental regulatory apparatus to insure the protection of the public and the environment. There are some countries though where these efforts have only just begun or where they are underfunded. These countries rely on international organizations for assistance, such as the FAO or WHO. The regulatory organization controls whether a pesticide is able to enter the market and the conditions under which it is sold. The regulatory organization sets standards for pesticides to insure that they can be used without harming individuals or the environment. It is said that the United States regulates pesticides through a risk-based system, while Europe uses a hazard-based system. In reality, both risk and hazard are assessed in the United States and Europe. The hazard-based system identifies a potential harm from a pesticide. The risk-based system evaluates potential exposure to the harm of the pesticide. It is challenging to identify the full range of potential hazards of a new pesticide. It is even more difficult to estimate the potential for exposure to the hazard and assess risk, and uncertainty is a factor in both assessments. Under the law that guides pesticide registration in the United

States, the EPA must consider whether the benefits of a pesticide outweigh the human health and environmental risks. As with risk, much of the data that regulators work with has an element of uncertainty. So safety factors are applied to reduce allowable exposure. The 1996 Food Quality Protection Act recommended, for example, that an additional ten times safety factor be applied to pesticide tolerances to protect infants and children. Ethics enters into the decision-making process for pesticide regulation in each of these areas. Should we concern ourselves with hazard or risk or a combination of the two? What role should benefits play in consideration of the registration of a pesticide and what sort of benefits should be taken into account? If regulators and the public consent to risk, what level of risk is acceptable?

The World Commission on Ethics, Science, and Technology (COMEST), sponsored by the United Nations Educational, Scientific and Cultural Organization (UNESCO), suggests that the precautionary principle should be employed in decisions like pesticide registration. COMEST defines this principle as follows: "When human activities lead to morally unacceptable harm that is scientifically plausible but uncertain, actions shall be taken to avoid or diminish that harm. Morally unacceptable harm refers to harm to humans or the environment that is

- Threatening to human life or health, or
- Serious and effectively irreversible, or
- Inequitable to present or future generations, or
- Imposed without adequate consideration of the human rights of those affected."

COMEST goes on to say "the moral implications of both action and inaction" should be considered (World Commission on Ethics, Science, and Technology 2005). There are many examples of pesticides that have been released for agricultural use only to be later banned or restricted, as unanticipated harms are realized. Current controversial examples of unanticipated harms are the purported drift of a supposedly less volatile version of the herbicide dicamba and the effect of neonicotinoids on pollinators. Pesticides that are banned or severely restricted in Europe continue

to be used in the United States, such as atrazine and chlorpyrifos, indicating differing assessments of potential harm or possibly differing political environments. Differing regulatory decisions in the face of sophisticated data and uncertainty seems to provide support for an approach like the precautionary principle. In Europe, chemicals that are judged to be a hazard to human health or the environment should not be allowed in the market if there are suitable alternatives. This is not the case in the United States where cost and benefit analysis is the focal point for decision-making. But, it's difficult to incorporate issues of morality and the complexities of risk uncertainty in a cost benefit analysis. Cost benefit analyses tend toward economic factors, with attendant difficulties in economic valuing of environmental costs. The COMEST statement on the precautionary principle also includes concern about intergenerational equity. This issue has been raised amid worries about climate change, but it also applies to pesticides and the environment. When pesticides eliminate a species, reduce biodiversity, or significantly alter the productivity of an ecosystem, later generations suffer the harm of loss of access to these goods. It is also difficult to adequately account for fairness between generations of access to a healthy environment in a cost benefit assessment.

In a democratic society, regulators must represent the public interest as members of government. Communications, both from and to the public, are a significant part of that responsibility. Regulatory actions are often preceded by a period in which comments are solicited from the public. Manufacturers and regulatory officials have the responsibility together to produce labels and product information that lead to the safe and best use of pesticides. Growers and regulatory officials have the responsibility to provide information about pesticides that allows for educated, fully informed consumption of agricultural products. Regulatory officials also must insure that communication about pesticides is complete and not misleading. This is critical on pesticide labels but also in pesticide sales literature and advertising. Space and time in popular media advertising is too limited to provide a considered rationale for

pesticide use and has the potential to drive poor pesticide decisions.

Conclusion

Pesticides are a critical feature of what has been called industrial agriculture, as they are necessary to maintain the yield of large monocultures that are dependent on external chemical inputs. It is argued that the increased yields of this kind of agriculture are increasingly necessary to feed the world's growing population. It has also been suggested that this efficient use of arable land allows preservation of more land for non-crop uses, such as wildlife conservation. The contrary view is that industrial agriculture is extractive and unsustainable and that pesticides are an enabling force. To what degree, if at all, do pesticides contribute to intergenerational inequity in food production? Is this generation leaving land for the next generation that will be just as productive in the future?

Pesticide use varies regionally and by crop. Some crops receive very limited pesticide treatment, while others, like corn and soybeans, are heavily treated with pesticides. Pesticides undoubtedly contribute to yield increases in many crop systems. But, pesticides are not always used most efficiently and to best advantage. Pesticides are often applied in a prophylactic approach, whether the pest is present or not. It is possible though that in that particular season, the pest would not have developed in numbers that would threaten the yield of the crop. In this case, the prophylactic treatment was an unnecessary use of pesticide. The alternative to prophylactic treatments is to monitor for pest organisms and to apply pesticides only when the organisms reach an economic threshold that threatens the viability of the crop. The use of monitoring and economic thresholds (or the equivalent depending on pest) is part of a broader program to control agricultural pests called integrated pest management (IPM). Practices vary, but a good general definition is "an ecosystem-based strategy that focuses on long-term prevention of pests or their damage through a combination of techniques such as biological

control, habitat manipulation, modification of cultural practices, and use of resistant varieties. Pesticides are used only after monitoring indicates they are needed according to established guidelines and treatments are made with the goal of removing only the target organism. Pest control materials are selected and applied in a manner that minimizes risks to human health, beneficial and nontarget organisms, and the environment" (UC IPM n.d.). One of the merits of the IPM system is that because alternative controls are encouraged, and pesticide use is limited, there is a lower chance of developing pest resistance to insecticides – or at least it will develop more slowly. Pesticide resistance has been a significant problem in pesticide use. Critics of pesticides called it "the pesticide treadmill." Pests develop resistance to a pesticide over time, causing the grower to use increasing amounts of the pesticide to achieve control. Eventually, the grower must replace that pesticide with another, and the resistance cycle begins again. Another benefit of IPM is that it uses pesticides selectively and thus generally (though not always) in lower amounts. So, why isn't everyone using IPM? Obstacles include insufficient access to expertise in developed countries and the difficulty of collective grower action and limited training in developing countries (Parsa et al. 2014). If IPM delivers on its promise of lowered pesticide use, and lower impact on human health and the environment, then it would seem that there is an obligation to facilitate the adoption of IPM techniques.

Adopting integrated methods to manage pests and the use of pesticides is part of the broader approach of sustainable agriculture. Sustainability is presented as a bridge between agriculture and environmental ethics (Thompson 1995). This is sustainability not just in the sense of maintaining productivity for future generations but also in maintaining a healthy environment – and the two may be connected. This sort of sustainability represents a good that is an objective for action in agriculture. The ethical use of pesticides through an approach like integrated pest management, which eliminates or minimizes harms to human health or the environment, supports the larger moral goal of sustainable agriculture.

Introduction

While “pets” (hereafter, “companions”) would traditionally have been, and occasionally continue to be, fed primarily on leftover human food, it is now much more typical in the West for companions’ guardians to purchase or prepare “pet food” – particular foodstuffs designed with companions in mind. Recipes for dog food were being published as far back as the eighteenth century, and commercial dog food was first developed in the nineteenth century, with commercial cat food available by the 1930s (Sandøe et al. 2016, pp. 16–17). The rise in dog and cat food was influenced by a curious combination of health concerns: first, commercial pet food was presented as more healthy for companions than human leftovers, while, second, an increasing focus on the quality of human food meant that slaughter processes came to produce more waste products, which could then be made into pet food (Sandøe et al. 2016, pp. 16–17). Foodstuffs for companions other than dogs and cats have subsequently become available, and commercial pet food is now a lucrative, globalized business: the European Pet Food Industry Federation estimates

that the European Union contains 80,000 people directly employed in the pet food industry, which is worth €15 billion a year (FEDIAF 2014). Worldwide, the pet food market is likely to grow in the coming years and is the biggest single expenditure related to companion animals (Sandøe et al. 2016, pp. 261–262).

Companion animal diet has received only limited attention in animal ethics, and less still in the ethics of food. Given the numbers involved, as well as the growing interest in both the ethics of food and animal ethics, this is regrettable. There are, broadly, two kinds of obligations at stake when it comes to feeding companions, but these may seem to pull in different directions – guardians have an obligation to feed companions an appropriate diet and a simultaneous obligation not to feed companions a diet which conflicts with their duties to others. More specifically, there are at least three questions to answer when assessing the ethics of pet food: first, whether and to what extent the state is obligated to aid in the feeding of companions, second, if and how feeding companions might be wasteful, and, third, whether feeding flesh to companions violates duties to other nonhuman animals, and, if so, what alternatives there might be.

Obligation to Feed

Easy to acknowledge is that guardians have an obligation to care for their companions. A key part of this obligation is ensuring that companions are fed a diet which is at least sufficient for them to meet their needs – that companions are not left malnourished or ill. (It is worth noting that, in the Western context, overfeeding is more frequently a problem than underfeeding.) Precisely what constitutes a diet that will not leave companions hungry, malnourished, or ill is a question best left to veterinary nutritionists, and so is beyond the scope of the current piece. A more controversial possibility is that guardians have an obligation to provide companions with a *preferred* food, or at least a choice over foods. This may not be as demanding as it first sounds; such a duty may manifest itself fairly straightforwardly in guardians choosing not

to purchase foods that companions have previously rejected, if any.

A more difficult normative issue concerns the extent to which the state should be involved in guardians' obligations to feed companions. This question ties closely to the question of what responsibilities, if any, the state has towards or concerning companions more broadly. There are a wide range of possible answers to the question of state involvement in companion diets/pet food, ranging from the possibility that states should not be involved at all to the suggestion that needy companions are (at least) as entitled to food aid as needy humans. A snapshot of this spectrum follows.

At one extreme, it might be that feeding one's companion is a personal matter to the same extent that changing the oil in one's car is a personal matter. Even if we have some kind of ethical obligation to care for some or all of our property, this is not the business of the state, and the state should not spend its limited resources aiding individuals in caring for their property or policing what individuals do with their property. Ultimately, it might be argued, our companions *are* just our property, and if we are unable to adequately care for them, so much the worse for us. Others can choose to help us if they like (perhaps by donating to charities that will provide companions with food if they need it) but the state should not be involved. This position is one that has traditionally been, and occasionally continues to be, adopted by some liberal and libertarian thinkers. Such thinkers may or may not endorse the claim that guardians have a *moral* duty to (appropriately) feed their companions, but they will deny that the individuals' moral duties are any business of the state.

Many are dissatisfied with the simple equivocation of companions with other items of property, as it seems that one can wrong the companion *herself* in a way that one cannot wrong (say) a table *itself*. Poisoning one's dog is not the same as putting diesel in a petrol-fuelled car, and refusing to feed one's cat is not the same as refusing to water one's bonsai. Dogs and cats are capable of suffering and of having their interests set back; bonsais and cars are not. Additionally, it can be

argued that the state has some duties *concerning* companions (i.e., *indirect* duties), regardless of duties *to* the companions (i.e., *direct* duties). Many in Western democracies are concerned about the welfare of companions, and the state may have an obligation *to these people* to offer some protection to companions. For one or both of these reasons, Western states typically have institutions in place that can remove misfed companions from their guardians, and laws in place which can result in the prosecution of guardians who misfeed their companions. In addition, laws can be instituted at the production level, ensuring that appropriate and nutritious material is being used to produce commercial pet foods and that manufacturing processes do not risk contamination. The censure of unethical marketing practices is another possibility; humans (and, indirectly, companions) clearly have an interest in being protected from misleading claims about the benefits of particular pet foods.

Normative thinkers concerned with aiding needy companions or preventing unethical treatment of companions can endorse an expansion of these kinds of laws and state-supported institutions. So, for example, some theorists argue for an expansion of the licensing schemes which already exist in some countries (e.g., Cochrane 2012, Chap. 6). Institutions could be established meaning that only those with a license may be guardians, and the understanding and resources necessary to adequately feed a companion would be a prerequisite for license acquisition. Conversely, failing to adequately feed a companion could constitute grounds for the revocation of a license. This kind of (negative) protection could be complemented by (positive) aid; perhaps the state could be held responsible for providing food, vouchers, or money for the guardians of companions in need, analogous to how greater benefits will be provided to needy guardians of dependent humans (children or adults) than will be provided to needy individuals who do not have responsibilities for others.

A prominent recent proposal takes this kind of thought to its conclusion with the suggestion that companion animals be considered co-citizens (Donaldson and Kymlicka 2011). In recognizing

companions as citizens, argue Sue Donaldson and Will Kymlicka, we must accept “their equal right to communal resources and the social bases of well-being” (2011, p. 142). As such, the state should not be concerned with merely protecting companions from mistreatment through inappropriate feeding or even with merely helping needy guardians feed their companions. Instead, the state should be concerned with the companions’ own rights to food and the benefits of the society of which they are a part. On this picture, the state should have all of the same responsibilities concerning the feeding of companions as it does with ensuring the feeding of humans; indeed, given the relative vulnerability of companions to the whims of their guardians, the state would likely have even *more* responsibility over the diets of companions than it does over the diets of (most) adult humans. State obligations concerning companion diet become more like state obligations concerning the diets of children. On this picture, companion malnourishment, obesity, and associated issues become pressing sociopolitical concerns.

Limitations on Feeding

Companions’ guardians, then, likely have some obligation to ensure that their companions are appropriately fed, but the extent to which the state may have a similar obligation is contested. A second aspect of the ethics of companion animal diets arises when one asks if guardians’ obligations to third parties limit what they may feed companions. There are a number of ways to approach this question. First, and most simply, is (what could be called) the *libertarian approach*. This suggests that one can feed any food to companions, provided that it is acquired in what would be considered a just way to acquire human food; e.g., in accordance with any moral, legal, or political obligations individuals have to support fair trade, animal welfare, or sustainability. While plausible, the libertarian approach warrants little consideration here, as it entails that pet food does not raise any particular normative concerns in this area; as such, it will be addressed no further. The

second and third approaches, which can be labeled the *humanist approach* (HA) and the *animal rights approach* (ARA), respectively, require lengthier examination.

Limitations on Feeding: The *Humanist Approach*

Proponents of the HA observe that the production of pet food requires the use of limited resources, or else does some bad for which there is limited countervailing good. So, and the significance of this claim will become clear, the HA leans on the claim that companions are not themselves particularly valuable/worthy. There are numerous “faces” of the HA; four can be usefully demarcated. First, companions consume large amounts of food which could instead be fed to humans. Second, guardians spend a large amount of money on pet food which could be given to “worthier” causes. Third, pet food contains nonhuman-animal-derived products, and animal agriculture is associated with serious environmental problems. The fourth possibility draws upon the so-called animal welfare ethic (cf. Garner 2013, Chap. 5). This is the idea that, though nonhuman animals have *some* moral standing and are owed *some* duties, painless killing is acceptable, and so too is the infliction of suffering, provided it is “necessary” for some human end. While the production of human foodstuffs would typically be considered a “worthy” end, it might be said that the production of pet food is not. These challenges each warrant consideration.

The first challenge – that food could and should be fed to needy humans and not companions – does not have the scope that it may appear to have and can instead target only a relatively tiny volume of pet food. Most commercially available dog and cat food is made up of meat unsuitable or undesirable for human consumption, including slaughter by-products such as animals’ feet, flesh from animals dead or disabled prior to slaughter, and so forth (Sandøe et al. 2016, p. 221). Other components include plant matter and fats such as tallow; relatively plentiful, basic products. In this sense, then, “the

production of this kind of companion animal food does not appear to compete directly with the human food supply, given current tastes about which parts of animals are normally eaten” (Sandøe et al. 2016, p. 222). The challenge is blunted, but one may nonetheless insist that there is a problem given that *some* ingredients in commercial pet food could be fed to humans (especially with fish-based pet food), and given that some companions are fed higher-quality foods by their guardians. *These* pet foods, it may be said, remain problematic, and so guardians may have a moral obligation to ensure that their companions are not fed these more problematic foods. Given the humanist assumptions, this is plausible; while pet food is – assuming its wastefulness – not a *major* cause of food waste, it is conceivable that an increasing demand for (especially “high quality”) pet food will have some negative impact on the quantity of food available for humans. However, “at present, there is no substantial evidence that cat and dog food is in any major way competing with, or having serious impacts on, the human food supply” (Sandøe et al. 2016, p. 223).

Concerning the second face of the HA, it is certainly possible that the money spent on pet food could be put to alternative (“better”) use, that is, that it could be spent on causes such as alleviating human hunger. This challenge seems to be to the institution of companionship generally, rather than to pet food specifically. Pet food is by no means the only expenditure on companions – toys/accessories, veterinary bills, and the companions themselves all cost considerable amounts of money. Unlike, perhaps, some expensive veterinary bills (Hadley and O’Sullivan 2009), pet food expenditure cannot be separated from the institution of companionship. This is because humans who voluntarily take on a companion have a responsibility to ensure that she is adequately fed. There seems to be something morally suspect (or at least confused) about someone who takes on a companion but then allows her to become malnourished or ill because the guardian believes that she has a duty to donate the money she would spend on pet food to alleviate human hunger. On an individual level (and a

similar point could be made concerning the first face of the HA), this could be understood in terms of special versus general obligations (i.e., the historical or personal relationship the guardian has with companion could justify or even necessitate her spending money on the companion rather than on some distant stranger).

On a sociopolitical level, the question is more complex and will rest strongly on the question of the state's relationship with companions discussed in the previous section. The argument *could* be made that we have an obligation to abandon the institution of companionship altogether, given the financial (and other) costs, and instead put this money to a worthier use, but this is a very large claim; any response, presumably, would draw upon the value of companionship itself along with freedom of choice – issues which cannot be addressed here. A more moderate claim would be to say that those in the West have a duty to spend *less* on our pet food and to donate the remainder to worthy causes, but this seems to be a part of a broader argument about expensive Western lifestyles, and not an issue related to pet food specifically.

The worry that companion foods contribute to environmental problems, the third face of the HA, can be partially alleviated, as with the worry about the effect on human food supplies, with the observation that pet food is largely based upon by-products of animal industry. This said, companions “clearly use resources that add to global environmental problems such as habitat destruction and climate change” (Sandøe et al. 2016, p. 227). A large part of this comes down to pet food; not just its contents (including nonhuman-animal-derived content which is not a by-product) but its production process, its transport process, its packaging, and so forth all contribute to environmental degradation. This is a problem not easily sidestepped, and it could be that an obligation to be more environmentally conscious in our purchase and consumption decisions, as individuals or societies, points towards the need to rethink our pet-food-related practices. Again, though, one must ask whether this is – as it may have first seemed – genuinely a problem particular to pet food or just a relatively minor instantiation of a broader obligation.

The concern (the fourth face of the HA) arising from the ethic of animal welfare is an interesting one, as it points strongly towards the concerns of the ARA discussed shortly. Furthermore, it is a challenge, unlike some of the other faces of the HA, which is somewhat specific to pet food. The thought is that if human consumption of nonhuman-animal-derived products generally entails suffering, this suffering is “necessary”, as it serves some putatively significant end. However, the production of pet food is not, one might claim, a sufficiently significant end, and so suffering in pursuit of this end is “unnecessary.” Two possible answers to this are unsatisfactory. First, we cannot (again) appeal to the fact that pet food is mostly made of by-products, as, even taking this into account, pet food necessitates substantial suffering. The use of small fish in cat food, for example, is particularly problematic, as a relatively large number of these animals are required to produce even a small amount of food, and more animals means more suffering. Second, an appeal to the *human* value that arises from companionship is unconvincing, as it is unclear that the value gotten from companionship depends upon feeding companions the products of this “unnecessary” suffering. Humanists adopting this fourth argument have identified a genuine concern about pet food, and one which is (relatively) specific to the issue. It is possible that a solution to this problem can be offered by the ARA, and it is to this that I now turn.

Limitations on Feeding: The Animal Rights Approach

For the ARA, there is a particular worry about pet food which comes not from the relatively low value/worthiness ascribed to companions (as in the HA) but to the relatively *high* value ascribed to nonhuman animals generally. So, while what might be called “animal advocacy” positions will (strongly) endorse the obligations of guardians to their companions – including their obligations to provide appropriate, healthy, preferred food – they will also endorse strong obligations to *other* nonhuman animals, including those who might be

used to produce foodstuffs. A problem thus arises when it comes to feeding nonhuman-animal-derived foodstuffs to companions. In social psychology, the term “vegetarian’s dilemma” is used to refer to the issue of reconciling “feeding one’s pet an animal-based diet that may be perceived as best promoting their well-being with concerns over animal welfare and environmental degradation threatened by such diets” (Rothgerber 2013, 2014). In applied philosophy, the same kind of concern has been dubbed the “animal lovers’ paradox”: given the fact that nonhuman-animal-derived products are fed to companions by animal lovers (the companions’ guardians), in some cases, it may be that one of the things that people could do to alleviate nonhuman animal death and suffering is to stop being animal lovers (Milburn 2016).

It should be noted that the fact that much of the animal-derived protein in pet food is from “waste” products cannot be used to sidestep this problem. There are two key reasons for this: first, many theorists of animal rights stress (and, in practice, vegans typically hold) that individuals should not be supporting animal agriculture (or, minimally, should not be supporting animal agriculture as it is currently practiced). Whether money is spent on products that would otherwise be going to waste or not is irrelevant; either way, financial support is offered to those who inflict suffering and death upon nonhuman animals, which in turn goes on to support and encourage further exploitation. Second, and especially given the emergence of thinking focused upon states and societies (rather than individuals) who are respectful of animal rights (e.g., Cochrane 2012; Donaldson and Kymlicka 2011; Garner 2013), animal advocates look forward to a future in which humans have eliminated (or at least grossly reduced) their consumption and use of nonhuman-animal-derived products, which would mean that the waste products would not be available at all.

The solution to the vegetarian’s dilemma and animal lovers’ paradox may, on one level, seem simple; the ARA should suggest that, just as it is (say many animal advocates) illegitimate to consume parts of nonhuman animals’ bodies or products derived from their bodies (milk, eggs, etc.),

so it is illegitimate to feed said products to our companions or allow them to eat these products (Donaldson and Kymlicka 2011, pp. 149–153; Milburn 2015, 2016). This encounters a problem when it comes to the question of companions who are “naturally” carnivores. Dogs – who are able to thrive comfortably on a vegan diet – are not a particularly difficult problem. Cats, on the other hand, may well be, insofar as it is possible that they are not well-suited to a vegan diet (Donaldson and Kymlicka 2011, pp. 149–153; Milburn 2015, 2016; Rothgerber 2013, 2014). Other companions – whom I do not have the space to here explore – may warrant separate analyses; reptiles are routinely fed other reptiles, for example. This is a practice which may raise normative issues of its own (Warwick 2014).

Accordingly, applied philosophers have explored a variety of possible methods, assuming the received wisdom that cats are unable to thrive on a vegan diet (a point of contention in the scientific literature on veterinary nutrition), for the accommodation of cats within an animal-rights-respecting state. These possibilities include letting cats hunt, feeding cats scavenged flesh, feeding cats flesh grown in laboratories, feeding cats the eggs of domestic birds (Donaldson and Kymlicka 2011, pp. 150–153), feeding cats the flesh of a small number of very large animals, feeding cats the flesh of naturally non-sentient (unfeeling) animals, and feeding cats the flesh of those animals who may or may not be sentient (Milburn 2015). Those who raise these possibilities, however, reject some entirely, and express concerns even about favored options. As such, the possibility of “selective extinctionism” – making cat companions extinct because they are simply incompatible with a respectful state – remains as a last resort (Milburn 2015; Wayne 2013). One possible practical solution is to endorse a multifaceted approach when it comes to companion diets. This might be the suggestion that, while we *as individuals* should remove nonhuman-animal-derived products from our dogs’ diets, we should merely *limit* the nonhuman-animal-derived products in our cats’ diets. Meanwhile, we *as societies* can move towards an animal-rights-respecting state by removing all unjustly

acquired nonhuman-animal-derived products from all of our companions' diets. While this is relatively easy for dogs, further research may be required when it comes to cats (Milburn 2016).

Conclusion

Ethical issues related to pet food are underexplored in animal ethics and the ethics of food. Nonetheless, pet food raises a number of questions tied to broader questions about the institution of companionship, nonhuman animals in political theory, and human obligations to eliminate wasteful consumption. As such, our claims about pet food will necessarily be informed by our answers to these other questions. Companion diets also raise some fairly unique normative problems, such as the issue of feeding cats (or other carnivorous companions) in a vegan state. Academic consensus seems to lean towards endorsing a higher moral status for nonhuman animals than they are currently offered in practice, meaning that questions about our normative obligations towards and concerning them are likely to become more prevalent in years to come. When it comes to the ethics of food, ethical questions about pet food are one significant part of this. Though traditionally – rightly – overshadowed by questions about nonhuman animals in human diets, questions about nonhuman animals' own diets can no longer be ignored.

Animal suffering; Ethics of eating; Factory farming; Preference utilitarianism; Speciesism; Vegetarianism

Introduction

Peter Singer became well-known internationally after the publication of *Animal Liberation* in

1975. His research is strictly connected with food and eating as he investigates the area of well-being of nonhuman animals in order to prevent their suffering. He wrote many relevant books in this field: *Animal Factories* (with coauthor Jim Mason in 1980); *In Defence of Animals*, a collection of essays by philosophers, scientists, and activists in the Animal Liberation Movement, published in 1985; and the more recent *The Way We Eat. Why our food choices matter* (with coauthor Jim Mason in 2006). According to philosopher Helga Kuhse, Singer is “almost certainly the best-known and most widely read of all contemporary philosophers”; yet he has also been hailed as “one of the world’s 100 most influential people” and “among the most influential philosophers alive,” but he has also been brandished “the most dangerous man on earth,” accused of being a “public advocate of genocide” for his theories about abortion, euthanasia, and infanticide. Born in 1946, Peter Singer grew up in a fairly typical “heavy meat-eating” Australian family. As a graduate student at Oxford University in 1971, he became a vegetarian after learning about factory farming; from then on, he focused his research, his teaching, and his philosophy on the importance of preventing suffering by a “preference utilitarian” perspective, in order to extend ethics beyond sentient beings. (For this reason his moral point of view is commonly known as “extensionism.”) As he wrote in his seminal book, which became the Animal Liberation Movement manifesto, “the aims of the movement can be summed up in one sentence: to end the present speciesist bias against taking seriously the interests of nonhuman animals” (Singer 1985). The fundamental moral issue of eating for Singer is not merely the fact that humans kill animals for food; rather, it is more the idea that the animals just have unhappy lives and humans are really doing this for something that they do not need to eat.

Eating Ethically

Eating is an ethical issue as it deals with animal well-being and suffering. But this habitude should not be generally considered as a “raising ethical

issue,” because “eating is even more essential than sex, and everyone does it, usually more than once a day” (Singer 2005). The first step in moral evaluation of eating and food choices is to increase everyone’s consciousness: the most evident problem – as Singer pointed out – is that humans are generally ignorant of the abuse of living creatures that lies behind the food they eat. They do not usually care, indeed, about the way the food they eat is produced, about the way nonhuman animals live and suffer in the industrial factories, as humans do not consider the environmental consequences of their feeding and the political cost of their choices at the market. As Singer wrote: “When we eat – or more specifically, when we pay for what we eat, whether at a farmer’s market, a supermarket, or a restaurant – we are taking part in a vast global industry. [...] Food production affects every person on this planet and untold billions of animals as well. It is important, for the sake of the environment, animals, and future generations, that we see our food choices as raising serious ethical issues and learn the implications of what we eat” (Singer 2005). Hence, on the one side, consumers have an ethical responsibility not only to choose accurately but also to be aware of the way their food is produced; on the other side, the big brands have a corresponding obligation to be more transparent about their suppliers, in order to make their customers informed about what they are eating. But in many cases the biggest food companies themselves do not know how they perform on these issues, betraying a profound lack of ethical responsibility on their part.

This human lack of interest for animal suffering is caused, for Singer, by a sociological shift, linked to the ethics of globalization and by the western and Christian tradition, which both accepted the idea that animals are essentially resources for human use and benefit: they should be considered as merely means or products – an interesting interpretation of this issue is suggested by Camosy, who unconventionally points out the possibility to match the Christian thought with Singer’s philosophy (Camosy 2012). In Singer’s words: “For most humans, especially those in modern urban and suburban communities, the

most direct form of contact with nonhumans animals is at meal time: we eat them” (Singer 2009). Moreover, “the use of animals for food is probably the oldest and the most widespread form of animal use. There is also a sense in which it is the most basic form of animal use, the foundation stone on which rests the belief that animals exist for our pleasure and convenience. If animals count in their own right, our use of animals for food becomes questionable – especially when animal flesh is a luxury rather than a necessity” (Singer 1993). Therefore, according to Singer, eating should be a moral issue because it concerns the possibility of someone’s suffering, and, from a benthamian/utilitarian point of view, “if a being suffers, there can be no moral justification for refusing to take that suffering into consideration” (Singer 2001).

Utilitarianism and Vegetarianism

In his early writings Peter Singer showed the possibility to ground a vegetarian philosophy on a utilitarian moral perspective: “I am a utilitarian. I am also a vegetarian. I am vegetarian because I am a utilitarian. I believe that applying the principle of utility to our present situation – especially the methods now used to rear animals for food and the variety of food available to us – leads to the conclusion that we ought to be vegetarian” (Singer 1980). The reason is quite simple: Singer is a utilitarian, and utilitarians typically focus on the moral imperative to improve well-being (or happiness or “utility”) and to avoid pain (or physical suffering). The fundamental moral issue in eating is, as observed above, animal treatment: “What are the implications of utilitarianism for our treatments of animals? When we apply utilitarianism to the issue of how we should treat animals, one vital point stands immediately. Utilitarianism, in its classical form, aims at maximizing pain and maximizing pleasure” (Singer 1980).

The focal point in this approach is, thus, the possibility to experience and feel pain and pleasure: “The capacity for suffering and enjoying thing is a pre-requisite for having interests at all, a condition that must be satisfied before we can

speak of interests in any meaningful way.[...] If a being suffers, there can be no moral justification to take that suffering into consideration. No matter what the nature of the being, the principle of equality requires that its suffering be counted equally with the like suffering [...] of any other being. If a being is not capable of suffering, or of experiencing enjoyment or happiness, there is nothing to be taken into account. This is why the limit of sentience [...] is the only defensible boundary of concern for the interests of others” (Singer 2001).

Emphasizing sentience is the first step, in Singer’s thought, towards an extensionist ethics, as it should causes the end of an anthropocentric “speciesistic” approach; granting a moral status to nonhuman animals – at least to some of them – also means considering them as individuals capable of choosing and acting with a purpose and a project. The first and the main purpose for a sentience being is – according to Singer – to experience (and cause) pleasure and to avoid suffering, unless there is a sufficient justification: this is one of the most basic moral principles, shared by virtually everyone. In this respect everyone can correctly say with Singer that almost all non-human animals are morally significant entities: they have moral standing like humans and unlike stones. Referring to Bentham, indeed, Singer wrote: “the question is not, Can they reason? nor, Can they talk? but, Can they suffer? That is indeed a crucial question to ask whenever we are talking about beings who are capable of suffering and one that is clearly relevant to how we should treat both humans and nonhuman animals. Can they suffer? Can they enjoy life? If so, they have interests that we should take into account, and we should give those interests equal weight with the interests of all other beings with similar interests” (Singer 2009). Here Singer’s argument, though appealing, is quite weak because of its arbitrary starting-point grounded in self-interest: “Is there any reason why we should accept that ethical judgments can arise only by way of universalizing self-interested decision-making?” (Buckle 2005).

A utilitarian focus on well-being is, moreover, classically understood as a balancing act: since it is not always possible to enjoy maximal

well-being – in many cases, indeed, one’s interests conflict with another one’s – everyone should act in order to balance interests and perhaps to maximize happiness while minimizing suffering: “The only principle of equality I hold is the principle that the interests of every being affected by an action are to be taken into account and given the same weight as the like interests of any other being [. . .]. The principle of equality of interests merely makes it explicit that, because the principle of utility is the sole basis of morality, no other principle will limit the application of the principle of utility, or affect the way in which it operates. [. . .] As I said in *Animal Liberation* – The basic principle of equality does not require equal or identical *treatment*; it requires equal *consideration*” (Singer 1980).

Yet the consistent application of the abovementioned principles seems to lead directly to vegetarianism or, at least, to the avoidance of factory-farmed meat. The argument here is disarmingly simple and linear:

1. In modern factory farms, animals who are raised and slaughtered for food suffer considerable pain (Singer and Mason 1980).
2. Humans could easily nourish their selves without eating nonhumans animals.
3. The only reason to eat flesh is the enjoyment of how they taste.
4. The gustatory pleasure is not a sufficient justification for causing torment and suffering.
5. So, it is morally wrong to produce and consume such products.

That is to say: “If we are prepared to take the life of another being merely in order to satisfy our taste for a particular type of food, then that being is no more than a means to our end” (Singer 1990). But, as Cora Diamond points out, a similar approach is to a certain extent reductive and constraining, because it “makes it hard to see what is important either in our relationships with other human beings or in our relationship with animals” (Diamond 2004).

The utilitarian’s argument for vegetarianism is quite simple – but surely more effective – than the one proposed by Tom Regan and the promoters of

animal rights, as it shows how pleasure and suffering are strictly connected with sentience, without introducing any other elements (such as “duty” or “right”) in order to protect interests.

This is, precisely, one of the most criticized arguments by Singer’s opponents: the same reasons that lead someone to reject unfair treatment for animals are not strong enough to encourage changes in his lifestyle: “Critics allege that while utilitarians and consequentialists generally may oppose conventional animal productions, their theoretical basis for opposition doesn’t warrant individual dietary change” (Almassi 2011).

Vegetarianism: Change Your Philosophy, Change Your Life

Once one has clarified the reasons why it would be immoral to eat meat, it is necessary to translate these reasons into concrete ways of acting, in order to change things. But Singer’s thought is quite different from traditional vegetarianism, as it focuses not so much on the need to not eat meat, but rather on the moral obligation to prevent pain and suffering of nonhuman animals: “Some writers [. . .] think of vegetarians as immoral absolutists, who will stick to their belief in the immorality of eating meat no matter what. Thus Cora Diamond writes: – one curious feature of the Peter Singer sort of argument . . . is that your Peter Singer vegetarian should be perfectly happy to eat the unfortunate lamb that has just been hit by a car –. Why is this curious? Is it only curious on the assumption that vegetarians must think it *always* wrong to eat meat” (Singer 1980).

Peter Singer, thus, is not an absolutist vegetarian: he embraces vegetarian philosophy as the only possible way to support the interests of a larger number of sentient beings; in this respect, “the answer is to boycott all meat and eggs produced by large-scale commercial methods of animal production, and encourage others to do the same. Consideration for the interests of animals alone is enough justification for this response, but the case is further strengthened by the environmental problems that the meat industry causes” (Singer 1998). Even more: “*Merely* becoming a

vegetarian, without doing anything else to change our treatment of animals, may have no effect at all. But I do not advocate this passive form of vegetarianism. I advocate vegetarianism as something which underpins, makes consistent, and gives meaning to all our other activities on behalf of animals” (Singer 1980).

Ethics, Food, and the Environment

Human choices about food are intrinsically moral for another important reason: they should have a more or less negative impact on the environment: “Environmentalists are increasingly recognizing that the choice of what we eat is an environmental issue” (Singer 1998). The reason is quite simple: “Animals raised in sheds or on feedlots eat grains or soybeans, and they use most of the food value of these products simply in order to maintain basic functions and develop unpalatable parts of the body like bones and skin. To convert eight or nine kilos of grain protein into a single kilo of animal protein wastes land, energy, and water” (Singer 1998). Nowadays, agriculture is a major source of greenhouse-gas emissions and also one of the sectors most at risk from climate change: these are the two most important topics to be taken into account when it is necessary to express a moral judgment; grazing ruminant animals, like cattle and sheep, also contribute significantly to climate change. The moral question goes as follows: are humans still able to afford this luxury on a crowded planet with a growing human population? The more realistic answer is negative: “Intensive animal production is a heavy user of fossil fuels and a major source of pollution of both air and water. It releases large quantities of methane and other greenhouse gases into the atmosphere. We are risking unpredictable changes to the climate of our planet – which means, ultimately, the lives of billions of people, not to mention the extinction of untold thousands of species of plants and animals unable to cope with changing conditions – for the sake of more hamburgers. A diet heavy in animal products, catered to by intensive animal production, is a disaster for animals, the environment, and the health of those who eat it” (Singer 1998).

Obesity: Weigh More, Pay More

For a similar reason, it is possible to consider even obesity as an ethical issue, because an increase in weight by some imposes costs on others; these costs are not only “financial costs” but also “environmental” ones: this is the main reason that brings Singer to the ethical condemnation of obesity. The author reports a number of examples to strengthen his thesis: the higher environmental impact of fuels for transports, for example, an increase in the use of jet or train fuel implies higher greenhouse-gas emissions, which could make worsen the condition of global warming, and the necessity to build new infrastructures – when people get larger and heavier, indeed, fewer of them fit onto a bus or train; moreover, hospitals must order stronger beds and operating tables, have to build extra-large toilets, and so on.

These facts are enough, in Singer’s mind, to condemn obesity and to justify public policies that discourage weight gain, for example, by taxing foods that are disproportionately implicated in obesity. These policies may also help in obtaining two positive consequences: discouraging their consumption by people who are at risk of obesity and using revenue raised to offset the extra costs that overweight people impose on others. In a utilitarian perspective, obesity is an ethical matter, that is to say it should be considered not only as a personal issue but as a universal one: valuing both human well-being and environmental health, human weight is everyone’s business.

Factory Farming and Animals Treatment

“The case against using animals for food is at its strongest when animals are made to lead miserable lives so that their flesh can be made available to humans at the lowest possible cost. Modern forms of intensive farming apply science and technology to the attitude that animals are objects for us to use. In order to have meat on the table at a price that people can afford, our society tolerates methods of meat production that confine sentient animals in cramped, unsuitable conditions for the entire duration of their lives. Animals are treated like machines that convert fodder into flesh, and

any innovation that results in a higher “conversion ratio” is liable to be adopted. [...] If we do not change our dietary habits, how can we censure those slaveholders who would not change their own way of living?” (Singer 1993). As Singer and Mason showed in their recent book *The Way We Eat*, in the United States alone, many billions of animals are killed each year for human consumption, almost all of them raised in “factory-farm” conditions in which their well-being is systematically sacrificed. A minimal decent life for animals, indeed, is not possible in CAFOs (Concentrated Animal Feeding Operations), because the main purpose of factory farms is to reduce expenditures and thereby maximize profits. As Singer wrote, it is not an individual’s problem, but rather a political (and economical) one: “The real ethical issue about factory farming’s treatment of animals isn’t whether the producers are good or bad guys, but that the system seems to recognize animal suffering only when it interferes with profitability. The animal industry always says that producers take care of their animals because what is good for the animals is good for the producer” (Singer and Mason 2006).

However, the real Singer’s purpose is to shed light on the condition of animals in factory farms in a very effective way, in order to make everyone think about the real standard of living of non-human animals (Singer 2010). In this regard, he shows how about 90% of US breeding sows spend today most of their lives locked in really tight cages, unable to turn around, and kept on short tethers; he highlights how, in the same way, veal calves are confined for all their lives in individual stalls that do not permit them to turn around, lie down, or stretch their limbs. The same goes for chickens, which cannot move around “not because they are overstocked, but because it hurts their joints so much. Sometimes vertebrae snap, causing paralysis. Paralyzed birds or birds whose legs have collapsed cannot get to food or water and [...] die of thirst or starvation” (Singer and Mason 2006).

In this regard, the factory farm is nothing more than the application of technology to the idea that animals are means to human’s ends.

Food and Policies

For Singer’s purposes the philosophical thought should be made into political activism and militancy: this is the reason why humans should begin to see the purchase and consumption of factory-farm products, whether by an individual or by an institution like a university, as a violation of the most basic ethical standards of how they should treat animals and the environment. This is, nowadays, one of the big moral issues, and human beings are – in Singer’s mind – superficially overlooking it, focusing merely on issues like the use of embryos for research and gay marriage.

The issue should be analyzed and solved in social and political terms: the problem may not be with citizens’ attitudes, but rather that, at the federal level, the political system allows big industries too much power to frustrate the needs of popular majorities. Americans, indeed, seem to care just as much about animal welfare as Europeans do: thus, how is it possible to explain the gap between Europe and the United States on farm animal welfare? Looking at the political systems: as demonstrated by Singer, while in Europe the concerns of voters about animal wellness have been successful in persuading members of national parliaments, in the United States, similar concerns have had no noticeable effects on the Congress. While in Europe there are national legislations and EU directives that respond to the concern of animal welfare, in the United States there is no federal legislation and very little state legislation on this concern. The reason is quite simple for Professor Singer: in the US electoral politics, money counts for more than the opinions of voters.

Another fundamental moral issue with a huge political impact deals with agriculture: “No other human activity has had as great an impact on our planet as agriculture. When we buy food we are taking part in a vast global industry. Americans spend more than a trillion dollars on food every year. That’s more than double what they spend on motor vehicles, and more than double what the government spends on defense” (Singer and Mason 2006). This moral issue is two-sided: on the one side, customers have the moral obligation to buy locally and in season in order to save energy and transportation costs and to discourage the global

market; on the other side, it is needed to prevent the purchase of agricultural land in developing countries by rich ones with international policies.

Summary

In Singer's thought, eating is an ethical and a political issue together: it is an ethical issue as it deals with animal wellness and suffering; it is, indeed, a political issue since it concerns international policies regarding the environmental impact and the climate change, in large part influenced by our food choices. In this perspective, vegetarianism seems to be the only possible way to support the interests of a larger number of sentient beings in order to realize the preference utilitarian moral imperative.

Introduction

Modern plant breeding is based on the discipline of genetics that was founded in the nineteenth century when Gregor Mendel did his seminal hybridization work in peas to discover the basic laws of inheritance and segregation of traits in the offspring. This scientific progress allowed for a certain level of control over the genetic material in order to develop improved agricultural and quality traits. Over the past century, there has been a steady progression in our capacity to manage genetic resources in plant research and breeding, allowing both a higher capacity to generate useful genetic variation and a higher control of the desired genetic changes and combinations. The output in terms of yield increase for all our major crops has been astonishing.

Modern plant breeding thus relies on the advancements in various scientific disciplines such as physics, chemistry, biology, and not the least statistics. Many technical advances in molecular biology started already in the 1960s and 1970s, enabling in vitro construction of biologically active recombinant DNA in the early 1970s. These techniques represented a breakthrough, providing an unprecedented level of both control

and access to genetic resources. The power of the newfound tools made scientists themselves voice the concerns that these versatile techniques could have a potential to be biologically hazardous (Rogers 1975). However, it was also emphasized that the concerns were based on judgments of potential rather than demonstrated risk (Berg et al. 1974). When the first transgenic plants were developed in the early 1980s, and the technique was adopted by seed companies in the mid- to late 1980s, it triggered further discussions about biosafety assessments and regulation of commercial activities within the field of plant genetic engineering, and the first national/regional legislations for genetically modified organisms (GMOs) were established.

These early legislative frameworks were developed as a consequence of progress in recombinant nucleic acid technologies. However, more recent progress in molecular biology has provided a capacity for a continuum of controlled gene and genome editing ranging from single nucleotide changes to full-length gene insertions. This increasing precision represents another major change from conventional breeding approaches relying on randomly induced mutagenesis and relatively uncontrolled meiotic recombinations (EASAC 2017). However, the products of genome editing are sometimes impossible to distinguish from corresponding products resulting from conventional breeding or from natural mutations. This has caused a great deal of confusion lately regarding how to regulate the products of these emerging techniques. This entry discusses various existing and potential regulatory approaches to these emerging genome editing techniques and from a more general perspective also the role and governance of technical progress in life sciences within society.

Governing the Progress in Plant Breeding

Natural Genetic Variation

When the disciplines of molecular biology and recombinant nucleic acid techniques were first developed half a century ago, not much was yet

known about natural genetic variation or the extent nor mechanisms of cross-species exchange of genetic material that occurs in nature. However, we have now come to understand that genetic engineering as it is carried out by us humans, such as DNA recombination and genome editing, depends on similar molecular mechanisms as those yielding natural genetic variation. This variation can be attributed to three basic categories, which are local nucleotide sequence changes, intragenomic rearrangement of DNA segments, and acquisition of foreign DNA segments by horizontal gene transfer (Arber 2010). Horizontal gene transfer is a term that we should take a closer look at, because it tends to challenge common notions about species, about genes, and of evolution. When recombinant nucleic acid techniques were developed, they were considered to give us humans an almost unique capacity to blend genetic material of various origins. It may come as a surprise to many, though, that we are now discovering that cross-species and even cross-kingdom transfer of hereditary genetic material may be much more common than ever previously thought, with recent examples from sweet potato, a grass species, and the experimental model species *Arabidopsis* (for more information, see Kyndt et al. 2015; Vallenback et al. 2010; Novikova et al. 2016). It seems as though we have to give up the idea of a particular gene “belonging” to the very species where it is found and rather assume the fact that the very building blocks of the hereditary material are shared among all living organisms and that genes are indeed highly transferable among species.

Regulation of Genome Editing

Emerging techniques that allow precise and highly controlled genome editing provides plant researchers and breeders with very efficient and versatile tools; however they have also presented challenges to policy makers all over the world due to their apparent resemblance at the technical level to recombinant DNA, or GMO, techniques. Genome editing can be described as the deliberate alteration of a selected DNA sequence in a cell, using site-specific DNA nuclease enzymes (EASAC 2017), whereas the definition of a GMO,

as it is stated in several national and international legal texts, often contain references to recombinant nucleic acids and also that the genetic material should be altered in a way that does not occur naturally. The two key things then are (1) the limits of recombinant DNA and (2) what can and what cannot occur naturally.

Regarding the limits of recombinant DNA, it must be a question of detectability. A full-length gene insertion from another species is easy to detect when you know what to look for and you know the sequence of the inserted gene. Then it is possible to prove the presence of recombinant DNA. However, if only a single base pair has been altered through genome editing, then it is impossible to determine whether the alteration, or mutation, was created artificially in the laboratory or if it is the result of either a natural, spontaneous mutation event or even an induced mutation through the classical breeding approach using radiation or chemicals. The longer the base pair sequence that is being altered, the lower is the probability that it would occur naturally or via a traditional breeding method, and when reaching about and above 20 base pairs, it can be said with certainty that it is the result of artificial recombination.

Regarding what can or cannot occur naturally, we have seen already that our knowledge about horizontal gene transfer and other mechanisms of hereditary material flow in the nature has increased a lot since the days when the first GMO legislations were written. Any future legislation will have to take this into account and modify any definitions accordingly.

Regulatory authorities all over the world are currently discussing whether or not the emerging genome editing techniques should be covered by existing GMO regulatory frameworks. The European Union (EU) has not yet adopted any official position. A working group with member state representatives (New Techniques Working Group) was set up in 2007 to evaluate emerging techniques including genome editing, and the (unofficial) report from 2012 suggested that organisms that cannot be distinguished at the molecular level from those developed by conventional breeding techniques or from natural genetic

variation are not GMOs. Also the European Food Safety Authority (EFSA) explained in 2015, when asked by the European Commission (EC), that when genome editing techniques are applied to introduce minor genetic changes including only one or a few base pairs, they are indistinguishable from mutations introduced by natural or induced mutagenesis and can therefore also be considered a form of mutagenesis and thus not GMO (EFSA 2015).

Another major issue is whether legislation should focus on the particular technique that has been used in the development process or if the resulting trait is more relevant from a biosafety assessment perspective. Many GMO legislations from various countries and regions, including the EU, are sometimes considered typical examples of technique-based legislations, though it is also argued that an element of product is often involved as the resulting organisms and their derived products need to contain recombinant DNA for the GMO definition to apply. Nevertheless, the approach of looking at the resulting trait that is of ecological and/or health relevance, rather than the applied breeding technique, has recently been suggested by the Swedish government, as well as by a number of bodies such as the UK Biotechnology and Biological Sciences Research Council (BBSRC), the German Academies, the European Plant Science Organisation (EPSO), and the French High Council for Biotechnology (HCB).

In the USA, several products developed by genome editing have already been deregulated, including mushroom, oilseed rape, and the alternative oilseed crop *Camelina*. In the case of *Camelina*, the absence of fragments from known plant pests allowed the USDA to deregulate this crop. Canada has a different approach altogether, looking strictly at the resulting trait of the organism and its derived products regardless of which particular technique has been used in the breeding process, applying the risk assessment procedure if the trait in question is considered novel to the Canadian agroecosystem. Furthermore, Argentina has adopted a case-by-case approach where the key issue is the concept of “novel combination of genetic material,” to determine if a product

derived from an emerging technique is considered GMO or not (Whelan and Lema 2015). This approach was recently tested when the regulatory authorities of this country notified that a genome-edited soybean under development by a national company will not be regulated as GMO.

Risk Potential

What, then, about the potential for risk that was raised by scientists in the 1970s for recombinant DNA techniques? Is this risk potential also applicable to emerging gene technologies such as genome editing? After all, the purpose of legislation is to ensure safety for humans and for the environment, and in this context it is relevant to discuss the risk potential of novel technologies in relation to development of regulatory policies. Forty years of applications of recombinant DNA technology has beyond doubt demonstrated that there are no inherent risks with these techniques in themselves, but rather that all risks are coupled to the particular trait that has been modified. When it comes to genome editing, a recent explanatory note from the Scientific Advice Mechanism (SAM) to the European Commission (EC) explained that conclusions cannot be drawn about the absolute or comparative safety of techniques based on the predicted occurrence of unintended effects. An assessment of safety can only realistically be made on a case-by-case basis and depends on features of the end product. This explanatory note did not provide any policy recommendation; however it noted that genetically and phenotypically similar products deriving from the use of different techniques are not expected to present significantly different risks (SAM-HLG 2017). Also the similarity of the molecular mechanisms in genome editing compared with those resulting in natural genetic variation, as explained above, makes it reasonable to assume that the level of inherent risk in the application of gene technologies is comparable to that for natural biological evolution and for conventional breeding methods. These risks are known to be quite low (Arber 2010).

It is important to emphasize though that even crops that are developed through the use of conventional techniques, and hence that are not

encompassed by the GMO regulatory framework, are regulated to some extent. No cultivars or their derived products are completely unregulated. Conventional breeding is in most countries governed by the International Union for the Protection of New Varieties of Plants (UPOV). The mission of UPOV is to provide and promote an effective system of plant variety protection. The UPOV convention ensures that novel released cultivars are tested over several generations and that they have a distinct quality or trait, that the seed material is uniform, and that the traits are stable over generations. UPOV has 74 member states, covering almost all the Americas, Europe, Asia, Australia, and many countries in Africa.

Perceptions of Evolution and of Life

The emerging gene technologies have enormous potential and are potentially disruptive to society in the sense that they may catalyze a transition and establish novel industry potentials that will affect existing production structures. The progress in molecular biology and other life sciences may even go beyond that and present humanity with altered, or entirely novel, perceptions of biological entities, of evolution, and of life itself. It is therefore important that the progress and the applications are undertaken in a responsible manner, adequately informing and also, whenever appropriate, consulting all stakeholders including the general public. This kind of responsible innovation has been described as attending to ethical, legal, and societal issues while seeking to identify common goals. More specifically for genome editing, these goals range from the protection of citizens from possible health risks to moral and political interests around the acceptable limits to intervening in natural processes (EASAC 2017). What has also happened over the past few decades is that plant science has become an increasingly collaborative domain, including aspects of physics, chemistry, mathematics, and not the least computing. This combination of disciplines allows us to uncover complex biological situations, in an integrative approach called systems biology (Smykal et al. 2016).

One fundamental question that we should never cease to examine is what these emerging

techniques, as well as any future scientific progress, are doing to our abilities to control and modify the hereditary material in organisms and what the consequences of these abilities may be. Will this scientific progress in the field of life sciences eventually affect our common view of the building blocks of living organisms, of evolution, and even of the nature of life itself? Nobody is able to provide a satisfactory answer to that question, no more than Copernicus, Kepler, or Galilei were able to foresee the Newtonian revolution in our understanding of universal mechanics. A microbiologist exclaimed at the 1975 Asilomar conference that “Nature does not need to be legislated. But playing God does” (Rogers 1975). But what the words “playing God” actually mean depends to a large extent on the historical and cultural context. Only time will tell what will be the societal and ethical implications of the current gene technology revolution we are experiencing. There is reason though to look to the future with carefully considered optimism as this progress may provide us with the tools to set our human societies on a more environmentally sustainable path.

Conclusions

Controlled and science-based plant breeding started more than a century ago and has ever since then benefitted from progress in all major scientific disciplines, including chemistry, physics, biology, and statistics. This has provided breeders with an increasing level of control of the genetic material of crop plants. When recombinant DNA techniques were developed in the 1970s, it triggered biosafety discussions that eventually led to the first regulations of genetically modified organisms (GMOs). Recent technical developments enabling very specific targeted mutations, and thereby a high control over the traits, have now once again caused regulatory discussions. Whereas these emerging techniques share certain similar technical features with techniques leaving recombinant DNA in the organism, the final products are often indistinguishable from those of conventional breeding

or also naturally occurring variation. Parallel to the regulatory challenges, the progress in our ability to control the hereditary material of living organisms is also triggering ethical considerations and challenging our views of evolution, of what *natural* actually means, and of life itself.

Plant Sentience

Andrew F. Smith

Department of English and Philosophy, Drexel University, Philadelphia, PA, USA

Introduction

Arguably the most salient characteristic of sentience is the capacity for subjective awareness of sensations and emotional states that are pleasant or unpleasant (DeGrazia 1996, p. 99). Specifically, sentient beings have interests, preferences, and cares associated with avoiding pain, fear, and anxiety (Rowlands 2002, p. 11). They have unpleasant sensory experiences associated with actual or potential tissue damage, emotional responses to perceived threats to their physical or psychological wellbeing, and the desire to evade both.

Although it is generally assumed that only animals have these experiences, ample evidence exists to support the proposition that plants, too, are sentient. This is not a new proposition. It is a common view among animists that dates back many millennia, is a central principle of Jainism, and was defended by Aristotle's student and subsequent director of the Lyceum, Theophrastus (Hall 2011). But it has been out of favor even among plant scientists until quite recently. The bulk of the evidence in favor of plant sentience has been provided by specialists in *plant neurobiology*, which is a misnomer since plants do not have neurons, synapses, central nervous systems, or brains. For this reason, plant neurobiology is the subject of controversy among plant scientists (Alpi et al. 2007; Firm 2004).

But plants do possess a homologous information-processing system that integrates

incoming data – on light, water, gravity, temperature, soil structure, nutrients, microbes, herbivores, and other plants – and coordinates behavioral responses. Plant neurobiologists offer ample reason to accept that these are not simply automatic reactions to specifiable stimuli. This is not to say that the lived experience of plants is somehow the same as that of animals. Among other differences, plants' lives unfold in a much slower time frame than ours. So while plant neurobiologists use terminology to characterize plant behavior that is usually reserved for animals, they do not insinuate that we should regard the two as experientially interchangeable.

Sensation, Pain, and Homologous Systems

Chamowitz states that while the sensuous experiences of plants and animals differ qualitatively, due in part to the fact that plants have no discernible organ of perception, plants have sensuous capacities that are at least functionally comparable to our five senses. "Sight is the ability not only to *detect* electromagnetic waves but also the ability to *respond* to these waves" (2012, p. 24). Plants may not translate light reflecting off objects into images, but they do convert it into cues for physiological, morphological, and phenotypic development. They not only distinguish light from shadow but also track seasons and the time of day. It is no particular advantage for plants to see like we do, but it certainly benefits them to know the direction, intensity, and duration of light sources and potential obstructions to accessing it.

The only difference between taste and smell is that the former is dependent on solubles (by dissolution or liquefaction) while the latter depends on volatiles (on the inhalation of gases). Plants sense and respond to volatiles in the air and to solubles on their bodies. They are highly sensitive to pheromones, just as we are, using them for communication and signaling.

Plants also are able to hear. Appel and Cocroft (2014) have observed plants release defensive chemicals upon playing a recording of a caterpillar biting a leaf. One means by which plants distinguish self from other – yes, they exhibit

indicators of an internal sense of self – is through the recognition of unique oscillatory signals. The movements of each plant register on a frequency not shared by other plants (Gruntman and Novoplansky 2004).

Also like animals, the sense of touch is electrochemically mediated in plants. Plants' sense of touch is highly developed (Trewavas 2005). Roots know when they encounter solid objects. Bushes and trees alter their morphology in response to high wind exposure. This is an evolutionary adaptation that increases their ability to survive perturbations.

Plants do not need a central nervous system to have these sensuous experiences. Do they need one to experience pain and suffering? They do respond physiologically to leaf punctures from insect bites, being burned, and drought conditions in ways that are consonant with self- and kin preservation. "But plants do not suffer," Chamowitz remarks. "They don't have, to our current knowledge, the capacity for an 'unpleasant' [...] emotional experience" (2012, p. 139). Their responses to wounding are not the equivalent of an *ouch*, even if these responses do entail the modulation of their development. Indeed, plants do not have nociceptors: neurons that specialize in sensing noxious stimuli. Nociceptors exist to enable their hosts to withdraw from dangerous situations and alert their hosts to internal physical problems (Rachels 2004, p. 77f.). (The activation of nociceptors is not a conscious event per se, although the detection of noxious stimuli often is accompanied by conscious – typically painful – events.) Without nociceptors, it is not clear that these experiences are possible, Chamowitz concludes.

Why then do plants excrete endogenous opioids, most notably ethylene, when wounded or subject to stress (Bühner 2002, p. 197)? Why are they rendered unconscious by the same anesthetics that work on animals (Pollan 2013)? (Perhaps plants are not conscious in the sense of having something like subjective awareness of themselves experiencing the world, but they can be awake and aware of the world around them. Marder (2014, p. 182) notes that plants are much like us with respect to consciousness, at least in one sense. They sleep.) How they respond to

insect bites, fire, and drought may provide an answer. Plants cannot escape noxious stimuli, but they do send signals indicating that the environment has become dangerous. So perhaps some sort of pain analogue plays a communicative role within and between plants, warning other parts of the plant as well as neighboring plants to make physiological adaptations to increase their chances for survival. Such an analogue need not be qualitatively equivalent to pain in order to be functionally equivalent to it. This is what Chamowitz suggests at any rate (2012, p. 68; see also Dicke and Braun 2001; Weiler 2003; Trewavas 2005; Barlow 2008).

Furthermore, plants' electrochemical information-processing system is homologous to animals' neural network. When a plant is wounded or experiences stress, electrical signals that are similar to action potentials running along nerves are sent from one region of a plant to another via voltage changes across cell membranes. These signals induce a rapid change in hormone metabolism. Specifically, they elevate auxin levels (Barlow 2008). Auxins are a class of plant hormone with morphogenic qualities. They induce cell differentiation and regeneration at the site of injury and are secreted from cell to cell along sieve tubes, elongated cells of phloem tissue, which are akin to synapses (Volkov 2000; Thompson and Holbrook 2004; Trewavas 2007). Auxins play a crucial role in coordinating plant growth and behavior, sometimes via long-distance signaling (Struik et al. 2008, p. 369). When the plant is wounded, auxins often induce cell differentiation and regeneration of vascular tissue.

The system thus has neurotransmitter-like characteristics (Dziubinska 2003; Baluška et al. 2006; Brenner et al. 2007; Fromm and Lautner 2007; Baluška and Mancuso 2009). "At the molecular level," Brenner and his colleagues hereby note, "plants have many, if not all, the components found in the animal neuronal system" (2006, p. 414). According to Baluška (2010), electrical long-distance signaling and the existence of processes akin to action potentials in plant cells and tissue support the proposition that the sensuous abilities of plants are not limited in comparison to animals. Indeed, plants produce

several proteins found in animals' neuron systems, including acetylcholine esterase, glutamate receptors, GABA receptors, and endocannabinoid signaling components. But we should not make a fetish of neurons, Mancuso remarks. Neurons "are really just excitable cells" (quoted in Pollan 2013, p. 92). Plants have excitable cells too – particularly at the root apex of the transition zone.

Sessility, Modularity, and Self-Awareness

Philips notes that plant scientist Trewavas:

thinks the only substantive difference between us animals and our distant green relatives is how mobile we are. We're used to judging intelligence by actions, he says. It's what we do and say that reveal what goes on inside our minds. So plants, silent and rooted to the spot, naturally don't appear too bright. But they do move and they do react to the world around them, he says, and they do so in intelligent ways. Plants can assimilate information, calculate outcomes, and respond using a complex series of molecular signaling pathways that are remarkably like those in our own brains. (Philips 2002, p. 40)

Sessility is typically regarded as a disadvantage, since it purportedly prevents plants from escaping danger. But sessility may account for the greater genetic complexity of plants with respect to animals. Plants must respond with far greater precision to the conditions they face than animals, since animals have the option to relocate (Trewavas 2009). Sessility thus requires an extensive, nuanced understanding of one's immediate environment not just to address dangers but also to access light and acquire water and nutrients. No wonder plants have biochemical constitutions that permit them to identify specific insects from the taste of their saliva after being bitten, deter and poison predators, and recruit insects to perform services for them (Buhner 2002, p. 162).

Consider these three examples. Tomatoes that are subject to damage by insects and herbivores produce methyl jasmonate as an alarm signal. Plants in the vicinity detect it and prepare for attack by producing chemicals that defend against insects or attract their attacker's predators (Farmer and Ryan 1990). They do not do so when subject

to mechanically induced wounding, as from high winds. This indicates the capacity for discernment (Paré and Tumlinson 1999). Acacia trees excrete an unpalatable tannin to defend themselves when being eaten by animals. The scent of the tannin is picked up by other acacia trees, which then also excrete it (van Hoven 1991). And when attacked by caterpillars, some plants release chemical signals that attract wasps, who attack the caterpillars (Thaler 1999).

Plants' sessility also accounts for their modularity; the operational control of growth and behavior is devolved among thousands of meristems at the tips of roots and shoots (Baluška et al. 2005; Brenner et al. 2006). This too has advantages unavailable to animals. Plants may not be able to escape danger, but they can survive extensive damage. Their modular design permits plants to lose up to 90% of their bodies without dying. "Brains come in handy for creatures that move around a lot," Pollan states, "but they're a disadvantage for ones that are rooted in place. Impressive as it is to us, self-consciousness is just another tool for living, good for some jobs, unhelpful for others" (2013, p. 92). Plants have no irreplaceable organs, so being food is not necessarily a death sentence. "There's nothing like that in the animal world. It creates resilience," Pollan adds (2013, p. 92). Neither being sessile nor having a modular design entails sentience, of course. But they should not be taken as strikes against sentience either.

Among the core signatures of sentience is self-awareness: the capacity to distinguish self from other or, as DeGrazia puts it, "the ability to distinguish one's own body from the rest of the environment" (1996, p. 166). Available evidence suggests that this too is a capacity that plants have. Plants differentiate themselves from competing and noncompeting organisms and discriminate between kin and nonkin (Karban and Shiojiri 2009). The former capacity is on display when plants must determine whether to compete for or share scarce resources with neighbors (Gersani et al. 2001; Maina et al. 2002; Callaway et al. 2003). The latter capacity includes rejecting pollen contributed by plants with which the recipient shares an allele (Biedrzycki 2010).

Intelligence, Learning, and Intentionality

For sessile beings, the centralization of systems governing signal integration and response is a disadvantage. The decentralized character of these systems in plants is an extension of their modularity. Does this entail that plants lack the capacity for cognition? Along with phenomenologists and researchers of swarm behavior, a number of cognitive scientists and philosophers of mind reject the proposition that not just cognition but intelligent behavior must result from centralized processes. Marder suggests that intelligence “is not concentrated in a single organ but is a property of the entire living being” (2012, p. 1370). According to Trewavas, “nervous systems are not necessary; complex networks are sufficient to create intelligent behavior” (2012, p. 773; see also Schull 1990; Warwick 2001; Vertosick 2002). And Garzón and Keijzer (2009) contend that the “embodied cognition” of plants permits them to organize their behavior in complex and adaptive ways.

Stenhouse (1974) suggests that intelligence should be conceptualized as the adaptively variable behavior of an individual organism during its lifetime. Mancuso defines the term “very simply” as the ability to solve problems. Plants do both. Trewavas notes that “plants respond to an enormous variety of physical, chemical, and biological signals in the environment to maximize foraging for resources in two distinct but unpredictable environments: above and below ground” (2012, p. 773). This requires not just considerable physiological, morphological, and phenotypic plasticity but an acute awareness of one’s lived conditions as well. It also requires the capacity to process information from both biotic and abiotic stimuli in order to discriminate between positive and negative experiences, make predictive assessment, weigh trade-offs, and formulate informed decisions (Hutchings and de Kroon 1994; de Kroon and Hutchings 1995; Grime and Mackey 2002; Lyon 2006). Add to this the need to counter threats from predators and disease and the fact that “Mate selection is elaborate and underpinned by discriminating, complex

conversations that precede and follow fertilization” (Trewavas 2012, p. 773), and it becomes clear that explaining plant behavior in terms of tropisms – reflex reactions to external stimuli – alone is inadequate.

Among others, Trewavas and Mancuso both contend that plant intelligence may be quite similar to swarm behavior, exhibited in the comportment of bird flocks and insect and bee colonies. Swarm behavior is a manifestation of distributed intelligence, an emergent property of the organization of “mindless” individuals. Swarms are not coordinated by a central system. As Pollan states, “In a flock, each bird has only to follow a few simple rules, such as maintaining a prescribed distance from its neighbor, yet the collective effect of a great many birds executing a simple algorithm is a complex and supremely well-coordinated behavior” (2013, p. 92). As Seeley and Levien note, “It is not too much to say that a bee colony is capable of cognition in much the same way that a human being is. The colony gathers and continually updates diverse information about its surroundings, combines this with internal information about its internal state and makes decisions that reconcile its wellbeing with its environment” (1987, p. 39). A similar phenomenon takes place within plants. Meristems act as do individual birds in a flock or ants in a colony. They gather, assess, and respond to environmental data in local but coordinated ways that benefit the organism as a whole (Noble 2006, p. 113; Ciszak et al. 2012; Marder 2013, p. 169). Indeed, while brains may provide a centralized site of cognition, they operate internally in much the same way (Trewavas 2005, p. 414).

Especially when we humans are young, perhaps the most salient aspect of our intelligence is our capacity to rapidly absorb vast quantities of information. Until we reach puberty, we are learning machines, as it were. We develop memories through our experience, and we establish and modify behavior and make predictions about future events in consonance with these memories. Like all cognition, our memories have a biochemical basis. This also is the case for plants, who remember and learn as well (Bhalla and Iyengar 1999; Brenner et al. 2006).

Memory and learning in animals involve the development of new connections within the neural network, but this is not the only way that information is stored. Pollan remarks that immune cells remember their experience of pathogens, calling on these memories upon future encounters. So-called “epigenetic” effects from traumatic events can be passed to offspring, such as through genetic coding for specifiable levels of cortisol (Molinier et al. 2006). These are the sorts of biochemical processes that contribute to the development of memories by plants (Sung and Amisino 2000, 2004). Memories are thus inscribed in the bodies of plants rather than actualized in subjective consciousness, Marder asserts (2014, p. 33). Some plants learn faster than others, of course, but observed behaviors do not have the traits of innate or programmed responses. Plants even can be taught to learn more quickly and to better retain what they have learned (Gagliano et al. 2014).

With respect to making predictions, plants take great care to ensure that the energetic costs of possible actions do not exceed their anticipated benefits. Future sun and shade patterns are predicted based on the perception of reflected far-red light (Izaguirre et al. 2006). The Mayapple commits to a branching and flowering pattern early in its life, using an analysis of leaf and branch patterns above it to anticipate gaps and where light will land coming through them (Geber et al. 1997). The dodder, a parasitic and nonphotosynthetic plant, discriminates between potential hosts. Once a suitable host is chosen, it decides how many coils to make around it in order to optimize the return on energy investment (Kelly 1990). The stilt palm “walks” out of shade by differential growth of its roots (Trewavas 2005). And when fewer nutrients are found, plants are able to both accelerate root growth (Callaway 2002) and increase the rate of nutrient absorption (Jackson and Caldwell 1996).

After watching time-lapse photography of a bean plant growing, Pollan describes a “seemingly conscious individual with intentions” (2013, p. 92). A bean sprout actively searches for something to climb, but it does not just grow any which way until it encounters something

suitable. It seems to know exactly where to go long before making contact, perhaps through the use of echolocation or by sensing the reflection of light off its surroundings. Whatever the case may be, the bean sprout does not waste energy fruitlessly. “And it is striving (there is no other word for it) to get there: reaching, stretching, throwing itself over and over like a fly rod, extending itself a few more inches with every cast. [...] As soon as contact is made, the plant appears to relax; its clenched leaves begin to flutter mildly” (ibid).

Perhaps Pollan simply witnessed the results of tropistic biochemical reactions. Biochemical reactions, yes, but our brains make decisions in the same way. Tropistic, no, or at least this is Marder’s conclusion. “To be conscious is to intend something, that is to say to be directed toward the intended object. [...] In light of this definition, the intentionality of plants may be understood as the movement of growth, directed toward optimal patches of nutrient-rich soil and sources of light” (2012, p. 1367; see also Darwin 1880, p. 573). It involves the deliberate prioritization of some sources over others. Animals’ intentions, enactments of directness, are carried out via muscle movement. Intentionality in plants “is expressed in modular growth and phenotypic plasticity” (ibid; see also Hutchings and de Kroon 1994). Again, it pays in terms of survivability for sessile beings to be highly attentive to the context of growth and development. Vigilance and the capacity to respond as one’s context changes are key. Sometimes this requires noncognitive action, something akin to our instinctive drive to flee. Sometimes careful and focused cognition is in order. It would seem that plants do both, even if these actions generally occur in a time frame that we have difficulty discerning.

Teaching and Nurturing

Keystone species – ironwoods, for example – are usually large, elderly trees which contain more mass than any other plant in a given ecosystem. Each individual keystone forms an archipelago around it that contains scores of associated plants. The formation of archipelagos takes centuries.

How and why they form as they do is not well understood. As Stephen Buhner states:

Quite often, before it can establish itself in a new location, a keystone species must have a plant that goes first and prepares the way. These initial species, usually selected from among the community of plants that grow with the keystone plants, are the outriders, the plants whose emergence signals the movement of plant species in mass. [...] These plants move first and essentially determine what keystone plants will grow where and when. In this way, they act as “filters” through which keystone species are sifted. (2002, p. 181)

Outriders make note of the quality of the soil, water, and light and send a return signal to tell the keystone species where and when to send seeds. Neither wind nor animal dispersal can explain how these seeds move where they move, Buhner contends. “The distances are too far, the dispersal patterns too unusual. But by whatever means, the seeds answer the chemical call sent by the nurse plants” (ibid).

Once established at the new location, keystone species then call to them soil bacteria, mycelia, and the plants that constituted their previous archipelago. “As the plants arrive, the keystone chemistries literally inform and shape their community structure and behavior. This capacity of keystone species to ‘teach’ their plant communities how to act was widely recognized by indigenous and folk taxonomies” (ibid, p. 183).

Plants also can nurture other plants directly. In the Great Basin of Utah and Nevada, sagebrush nurses piñon pines until the pines are old enough to grow on their own. The sagebrush alters the soil chemistry and provides physical protection from the elements (Callaway 1995).

Plant Sentience: The Speculative Leap

Plants have an information-processing and response system that is homologous to a central nervous system, and they exhibit some key characteristics of beings who suffer. Evidence supports the proposition that they are self-aware and highly attentive to their environments, exhibit intelligence and intentionality, and can remember, learn, and even teach. Appealing to the parsimony

principle, “which is the cornerstone of scientific approaches,” Paul Struik and his colleagues assert that the kind of evidence cataloged here does not permit “unfounded philosophical speculation” (2008, p. 369).

Yet whether or not the consideration offered here violates the parsimony principle is itself a philosophical question, as is the merit of adhering to this principle in the first place. Inferring the sentience of other-than-human animals requires empirical evidence on a par with the evidence provided here regarding plants. But neither determination can rely on empirical evidence alone. Hall remarks that “our perception of plants depends heavily on our philosophical orientation” (2011, p. 35). At the end of the day, the need to take a speculative leap is a professional hazard that every philosopher must face. Marder infers plant sentience “from the fact that plants explore and pursue unevenly distributed resource gradients, assess environmental dangers from biotic and abiotic stressors and gather and constantly update various types of information about their surroundings” (2012, p. 1368). But do they *actually* explore, assess, gather, and update? These are signs of his leap.

For what it is worth, plants make up 99% of the biomass on Earth. They dominate every terrestrial environment. We animals are the outliers. Of course, it is possible that only we animals – indeed, just a subcategory of us – are sentient, but a shift in the burden of proof is overdue.

Introduction

Diets containing animal products predominate in the developed world. Fewer than 10% of persons in the USA follow a vegetarian-inclined diet; fewer than 3% are strict vegetarians who consume no meat, poultry, or fish; and less than 1% are vegans who consume no animal products (Vegetarian Times 2008). Furthermore, diets in the developed world are often characterized by heavy consumption of animal products – up to 250 pounds annually (Daniel et al. 2011). As the developing world industrializes, industrial animal agriculture is expanding, and dietary patterns are shifting towards the heavy consumption of animal products characteristic of the West (Delgado 2003). Despite these facts, the consumption of animal products has become the object of much moral scrutiny over the past few decades, because of animal welfare concerns, environmental concerns, public health concerns, and nutritional

concerns. A key supposition in moral arguments for partially or completely plant-based diets is that human beings can sustain healthy lives without animal products. Were diets excluding animal products significantly damaging to human health, then arguments for morally obligatory plant-based diets would be seriously weakened.

A large amount of nutritional science about plant-based diets, defined here as strict vegetarian or vegan diets, has accumulated in the past few decades, much of which indicates that plant-based diets are not only capable of meeting human nutritional needs but can actually provide health benefits as compared to omnivorous diets (see, e.g., American Dietetic Association 2009; Fraser 2009). However, plant-based diets are also associated with certain putative health risks, the most significant being the risk of protein deficiency, vitamin D and B12 deficiency, iron deficiency, and calcium deficiency – though these health risks are not necessarily unique to vegan diets (American Dietetic Association 2009; Dunn-Emke 2005). These risks may be invoked in discussions of food ethics as counting against the moral obligatoriness of plant-based diets for some or even all persons, either because such persons cannot obtain the necessary nutrients, can obtain them only with difficulty, or cannot reasonably be expected to have the knowledge to appropriately plan a plant-based diet (see, e.g., George 1994).

Furthermore, in recent years there has been an increased interest in the so-called Paleolithic diets (e.g., there are now a number of journals that study such “Paleo” diets), which are explicitly based on the premise that humans are best adapted evolutionarily to consuming a large portion of their calories from meat and also to avoiding certain foods such as starches (see, e.g., Cordain 2002). Because of these issues the nutritional adequacy of plant-based diets cannot be assumed as an uncontroversial starting point in discussions of food ethics, despite scientific agreement in general terms about their potential nutritional adequacy.

When engaging discussions about plant-based nutrition, it is important to view claims critically, since they often appear to be influenced by covert

value judgments or framing assumptions. At times these value judgments and framing assumptions are evident in published philosophical or scientific literature; they also appear in conversation with sufficient frequency to merit examination. This entry reviews some of these value judgments and assumptions and shows how they may affect discussions about the nutritional adequacy of plant-based diets, particularly in Western countries such as the USA where omnivorous diets predominate. The goal is not to settle debates about the nutritional adequacy of plant-based diets but rather to improve the quality of discourse about nutrition and food ethics by alerting the reader to what might be hitherto unnoticed, but potentially contestable, judgments present in the nutritional assessment of plant-based diets.

Are the Risks of Plant-Based Diets Scrutinized More Closely Than the Risks of Omnivorous Diets?

The adoption of animal products into the diet of modern humans or our ancestors is not something that occurred only after a comprehensive risk analysis was performed and indicated that such products pose no risk; in fact no dietary pattern is free of risk. When considering the nutritional adequacy of plant-based diets, then, the appropriate determination is one of risks and potential benefits *as compared to alternative dietary patterns*. Such determinations cannot be made appropriately if all relevant risks and potential benefits are not considered or are considered in a biased fashion whereby some are selectively under- or over-emphasized. A number of considerations suggest that plant-based diets may commonly be subject to differently stringent evaluation than omnivorous diets.

One such consideration is that the possible healthfulness of plant-based diets tends to be called into question while the possible healthfulness of diets containing animal products does not. For example, the American Dietetic Association (ADA) has published a position paper examining the nutritional adequacy of vegetarian diets (American Dietetic Association 2009) but has

not published a position paper examining the nutritional adequacy of omnivorous diets. While the ADA statement is favorable to vegetarian diets, including total vegan diets, the very fact that such a position paper exists demonstrates a presupposition that the nutritional adequacy of plant-based diets cannot be assumed—either by the ADA, or by the American public more generally, to whom the ADA statement might be addressed. While academic articles examining specific health risks associated with the consumption of animal products can be found in the nutritional literature (see, e.g., Sinha et al. 2009; Hebel et al. 2012), such articles do not appear (in most cases) to have prompted significant doubt or worry, either among nutritionists or the general public, about whether it is *possible* or *difficult* to be healthy on an omnivorous diet. Rather, the risks associated with the consumption of animal products are usually considered in isolation or else coupled with recommendations to change specific aspects of an omnivorous diet, such as increasing the percentage of fruits and vegetables, decreasing overall meat consumption, or replacing red meat with poultry or fish, rather than eliminating animal products from one's diet entirely (see, e.g., Sinha et al. 2009; Popkin 2009).

In contrast, academic articles specifically examining or even questioning the overall healthfulness of plant-based diets *at a categorical level* are comparatively easier to locate (Waldman et al. 2005; Weaver et al. 1999; Haddad et al. 1999; Ingenbleek and McCully 2012). Whereas the risks of consuming certain types or amounts of animal products may motivate discussion of how persons consuming animal products can be healthier, the risks of plant-based diets are often discussed in the context of whether persons following plant-based diets *can* be healthy or *how difficult* it is for them to be healthy. This difference in rhetorical framing is subtle but important. Even where nutritional assessments of plant-based diets conclude that they can meet humans' nutritional needs, the rhetorical posture often seems to be that such diets require positive nutritional justification: they are assumed to be risky, or at least of questionable healthfulness, until shown otherwise. As one article puts it: "The adequacy and nutritional

effect of diets based entirely on plant foods is still under investigation" (Haddad et al. 1999). Hence, plant-based diets per se may be thought to require positive justification in a way that omnivorous diets per se are not, even though there are nutritional concerns relating to both dietary patterns and even though there is consensus that plant-based can be healthful for persons in all life stages.

Furthermore, when the potential advantages of plant-based diets over omnivorous diets are discussed, they are usually framed as *potential benefits* of plant-based diets, rather than *potential risks* of omnivorous diets. Again, this difference in rhetorical framing is subtle but important: it gives the impression that plant-based diets are perhaps associated with some desirable things, rather than the impression that omnivorous diets are associated with undesirable things. In contrast, were these differences framed as risks of omnivorous diets, the rhetorical effect would be one of portraying omnivorous diets as possibly harmful in comparison to plant-based diets, with the predictable upshot of conditioning debates about food ethics in terms of the permissibility of imposing risk on one's self, one's children, or the public's health by eating animal products.

While plant-based diets are associated with some risks, 33% of adults and 17% of children in the USA are obese (CDC 2012), and the USA is currently struggling with a significant public health burden from a number of chronic diseases directly linked to diet in general and the consumption of animal products in particular (Walker et al. 2005). Plant-based diets compare favorably to omnivorous diets as concerns body mass index, hypertension, type 2 diabetes, certain types of cancer, and all-cause mortality (American Dietetic Association 2009; Fraser 2009). In light of these facts, the relative overemphasis in the academic literature on the risks of plant-based diets as compared to the risks of omnivorous diets may indicate a subtle cultural bias (Varner 1994a, b).

A second potential indicator of differential scrutiny between plant-based and omnivorous diets is the rhetoric of "appropriate planning." Any dietary pattern can be unhealthy if not planned appropriately. The overwhelming

preponderance of omnivorous diets and the public health burden of diet-related diseases in the USA suggest that many persons following omnivorous diets are not planning them appropriately. Nonetheless, the importance of appropriately planning a plant-based diet often seems to be overemphasized as compared to omnivorous diets. For example, one prominent nutritionist has claimed that it is “unethical for people to bring up their children as vegetarians, *unless they take great care to know what they’re doing*” (Singer and Mason 2007, at 226; see also George 1992). Similar statements concerning omnivorous diets are not generally made. Critics of plant-based diets might respond that more knowledge is required to appropriately plan plant-based diets as compared to omnivorous diets, but this is questionable. For example, it is not obvious that any special expertise is required to heed the ADA’s recommendation that “an assortment of plant foods [be] eaten over the course of a day” to provide adequate protein intake and variety (ADA 2009). As Gary Varner observes, “anyone who can learn the meaning of ‘legume’ and find the vitamin section in the supermarket can understand how to follow [plant-based nutritional] guidelines” (Varner 1994a, p. 35).

A third way in which plant-based diets may be subject to differential scrutiny is that their specific risks may be overemphasized while their specific benefits are underemphasized. Varner (1994a, b) has described how discussions of plant-based diets in the nutritional literature tend to devote more space to their risks than their potential benefits, sometimes ignore important research relating to their benefits, and may overemphasize the evidence supporting risks while calling into question the evidence supporting their benefits. Though more recent nutritional literature generally does a better job of discussing the benefits of plant-based diets, the overall amount of attention paid to risk as compared to benefit still seems disproportionate in many instances.

There are at least two reasons why the risks of plant-based diets may be scrutinized more closely than omnivorous diets. One possible reason is self-interest: most persons in the USA and developed world consume large amounts of animal

products and may be reluctant to change their preferred dietary pattern. A relative overemphasis of the risks of plant-based diets provides a reason against changing dietary patterns, since a person’s own health can be cited as a reason not to adopt a plant-based diet. A second reason derives from what has been termed the cultural theory of risk selection. Sociologists and psychologists studying risk perception have long observed that both individual and group attitudes towards risk are variable and conditioned by a number of factors in addition to the probability or nature of an adverse outcome (see, e.g., Douglas and Wildavsky 1983; Finkel 2008). Such factors include social values and the familiarity of the risk in question. When risk-bearing activities or situations are unfamiliar, or when such activities or situations do not conform with widely shared social values, risks tend to be regarded as higher. Consistent with these observations, the statistical normalcy of omnivorous diets and the fact that moral views often underlying plant-based diets are not widely shared at present both may result in plant-based diets receiving added scrutiny as compared to omnivorous diets.

Framing Assumptions and Value Judgments in the Assessment of Dietary Risk

In addition to the general level of scrutiny given to plant-based and omnivorous diets, an examination of the nutritional literature indicates that framing assumptions and value judgments also significantly impact the nutritional evaluation of plant-based diets. One type of framing assumption concerns the way in which plant-based diets are defined. Studies of plant-based nutrition have, until very recently, frequently used as study populations the so-called new vegetarians, such as macrobiotics, who are persons following particular and often restrictive versions of plant-based diets based on religious principles. Such persons may eschew certain plant-based food sources and/or supplements. Not surprisingly, studies of plant-based nutrition carried out in such populations may document certain

nutritional deficiencies, such as vitamins D or B-12 deficiency (Varner 1994a).

Even where nutritional studies do not focus on special subgroups of persons following plant-based diets, they often focus on the diets that people *happen* to eat and not the diets they *should* be eating from a nutritional planning standpoint. For example, a recent study found that vegans had a 30% higher risk of bone fracture than omnivores, but upon closer inspection, it turns out to be the case that many of the vegans in the study were not taking in adequate calcium and that the increase in fracture incidence for vegan diets disappeared after calcium intake was controlled for (Appelby et al. 2007). These kinds of findings are important for documenting the risks of inappropriately planned plant-based diets, but they cannot be generalized to plant-based diets per se. Nonetheless, there is a historical tendency in the academic literature to identify “new vegetarians” with *all* vegetarians (Varner 1994a), and this tendency is still evident in some recent published work (see Finch and Stanford 2004, p. 11).

Contestable value judgments may be involved in the definition of dietary risk itself. In some cases, dietary risk associated with plant-based diets is assessed based on dietary intake or bioavailability of key nutrients such as iron, calcium, or sulfur-containing amino acids (Lönnerdal 2009; Ingenbleek and McCully 2012). However, this can be a problematic way to assess risk. For example, the lower bioavailability of nonheme iron in plant foods may be compensated for in some cases by the comparatively higher iron content in these foods. For many consumers in developed countries for whom food availability is not an issue, simply increasing the amount of a food consumed can also compensate for lower bioavailability.

Furthermore, dietary intake might not always be a good criterion for risk assessment by itself.

As concerns iron, for example, increased absorption and decreased excretion can help to compensate for decreased dietary intake (American Dietetic Association 2009). Moreover, the adequacy of actual dietary intake needs to be assessed against an appropriate standard. For example, persons following plant-based diets

may need less calcium than is generally recommended, since calcium requirements increase with protein intake, since persons following plant-based diets generally consume less protein than persons following omnivorous diets, and since the US RDA for calcium was set based on an assumption that most persons would be following Western diets high in animal protein (Lanou 2009; see also Bhatia 2008).

In other cases, the risks of plant-based diets are defined by reference to biochemical indicators of questionable importance. For example, studies may assert that plant-based diets are associated with a risk of iron deficiency based on the finding that persons following such diets have lower serum ferritin levels than persons following omnivorous diets (Lisowska et al. 2006). While serum ferritin is often considered an important indicator of overall iron stores, vegetarians or vegans with low serum ferritin levels often have normal serum iron levels, as well as normal hemoglobin levels. Furthermore, the ADA notes that the “incidence of iron-deficiency anemia among vegetarians is similar to that of nonvegetarians” (American Dietetic Association 2009). Hence, the attribution of iron deficiency risk to persons following plant-based diets on the basis of low ferritin levels is questionable, as “the physiologic significance of low serum ferritin concentrations is uncertain at this time” (Craig 2009, p. 1629S).

Contestable value judgments may also be involved in dietary risk assessment because the risks of one dietary pattern may be assessed without reference to the risks of alternative dietary patterns. Dietary calcium intake provides a good example. One recent commentary (e.g., Weaver 2009) recommends dairy intake as an essential part of a healthy vegetarian diet, since in the author’s view persons are unlikely to achieve adequate calcium or potassium intake without it. This is a contestable claim, not least because the author explicitly defines “vegetarian diet” as one that does not include soymilk, despite the fact that fortified soymilk is widely available and can (notwithstanding calcium present in other plant foods or supplements) provide similar levels of calcium to cow’s milk, which provides the majority of calcium in standard Western diets.

A counterpoint response notes that the consumption of dairy products may be associated with a number of diseases, including prostate and ovarian cancer, some autoimmune disease, allergy, and otitis (Lanou 2009). Furthermore, Western countries, in which omnivorous diets predominate, and which have the highest protein and calcium intakes, also have the highest incidence of osteoporotic bone fracture, something known as the “calcium paradox.” Some commentators recommend a shift to an appropriately planned plant-based diet for *optimal* bone health (Lanou 2009; Anderson 1999).

Serum ferritin provides another example. The lower serum ferritin levels sometimes documented in persons following plant-based diets have been cited as a risk of iron deficiency. However, there is some evidence that serum ferritin levels are positively associated with cardiovascular disease (You and Wang 2005). Heme iron, but not nonheme iron, has also been associated with cardiovascular disease (Geissler and Singh 2011). Hence, the lack of heme iron in plant-based diets, and also the lower serum ferritin levels sometimes seen in persons following plant-based diets, can also be viewed as a possible benefit compared to omnivorous diets.

The framing of a risk can influence a person's perception of its magnitude. For example, the aforementioned 30% increase in fracture risk seen in vegans as compared to omnivores was reported as a relative risk. When this is translated to an absolute risk, the risk difference between vegans and omnivores was about 1% (Appelby et al. 2007). When presented this way, the overall magnitude of the risk looks much less serious than when presented as a 30% increase.

Finally, it should be emphasized that as concerns vitamins D or B12, their metabolites, calcium, and iron, studies may report conflicting results. For example, some studies find that persons following plant-based diets have low serum ferritin levels (Lisowska et al. 2006), while others do not (American Dietetic Association 2009). Even where unplanned or poorly planned diets are concerned, evidential value judgments are involved in determining whether sufficient evidence exists to say that a putative risk is real.

Naturalness and Evolution

Arguments about naturalness and evolution may also play a role in the nutritional assessment of plant-based diets. Both strong and weak forms of this argument are recognized. The weak form holds that even if supplements or fortified foods are capable of meeting nutritional needs on a plant-based diet, we should prefer omnivorous diets because supplements are unnatural, whereas sourcing these nutrients from animal products is natural. This form of argument is really just an application of the “natural is good” argument to the realm of nutrition. The argument that what is good or right can be defined in terms of what is natural, or that what is natural provides a good *criterion* for identifying goodness or rightness, has been substantially criticized in the philosophical literature and so will not be reviewed in any detail here. For example, it is arguably “natural” for humans to be both violent and prejudiced towards persons not like them, but both of these tendencies are arguably bad from a moral standpoint. Furthermore, it may be recommended that persons following omnivorous diets take vitamin supplements in some circumstances, and many foods (e.g., breakfast cereals) are vitamin fortified. Hence, arguments from naturalness may apply equally to plant-based and omnivorous diets.

A strong form of the naturalness argument holds that humans are best adapted from an evolutionary standpoint to eating meat and that the substitution of other protein sources and/or supplements for meat in the diet will be less healthful. This argument does not equate naturalness with goodness *per se* but rather holds that the most appropriate diet for humans is the one that is most conducive to our health or flourishing; that what is most conducive to our health or flourishing can be discovered through an examination of humans' ancestral dietary patterns and/or other evolutionary considerations; and that an examination of these evolutionary considerations shows a meat-containing or even meat-rich diet to be best.

This is the form of argument underlying the so-called Paleolithic (or Paleo) diets. Specific

components of Paleolithic diets may include high intake of lean animal protein; high intake of fresh fruits and vegetables, particularly green, leafy vegetables; the elimination of starchy vegetables, dairy, and all grains from the diet; increased intake of nuts and seeds; and the elimination of processed foods altogether (Cordain 2002). The present concern is with plant-based versus omnivorous diets, so the relevant question is whether large amounts of lean animal protein are nutritionally superior to plant-based protein with or without appropriate supplements.

There are two lines of argument supporting Paleolithic diets. The first is the empirical observation that modern, developed countries show high incidences of a number of chronic diseases not seen in less developed countries or in contemporary hunter-gatherer societies. The second is the supposition that humans are best-adapted genetically to eating a diet closely approximating what our ancestors ate prior to the development of domestic agriculture and therefore that the chronic diseases seen in developed nations are attributable to deviations from this diet (Cordain 2002). Limited direct empirical data support the conclusion that Paleolithic diets may help to lower blood pressure, decrease body mass index, and control blood sugar, particularly in persons who are obese and/or diabetic, compared to no dietary change (Lindeberg 2012). However, it is not presently clear which components of Paleo diets are most responsible for these benefits – such benefits may, for example, be attributable to overall caloric restriction instead of animal protein. Furthermore, most of the arguments supporting Paleolithic diets are indirect and not based on direct empirical data.

A number of counterarguments raise doubts about the plausibility of Paleolithic nutrition. First, the lack of “diseases of civilization” seen in modern hunter-gatherer societies, despite sometimes high intakes of animal protein and fat, may be attributable to a very active lifestyle and not the benefits of diet itself – a point which proponents of Paleolithic nutrition often indirectly note themselves. Second, proponents of Paleolithic nutrition may make contradictory claims concerning evolutionary adaptation, for example, by endorsing “thrifty gene” hypotheses to explain

humans’ storage of excess carbohydrates as fat while also maintaining that Paleolithic diets did not contain significant carbohydrate (Knight 2011).

Third, theories of Paleolithic nutrition are premised on the idea that humans’ genetic evolution stopped in Paleolithic times, but this is not necessarily true (Knight 2011). Fourth, Paleo proponents typically hold that hunter-gatherer societies consumed large amounts of protein and little if any starch. However, only a few hunter-gatherer societies, such as the Eskimo, obtained most of their nutrients from animal sources. In most cases plant foods, including starchy plant foods, formed a large part if not the bulk of hunter-gatherer diets (Milton 2000; Mercader 2009). Fifth, direct empirical evidence casts doubt upon the idea that an ideal diet contains large amounts of animal protein. As already discussed, a large amount of nutritional science shows that plant-based diets, when appropriately planned, can meet humans’ nutritional needs and furthermore that plant-based diets offer benefits as compared to omnivorous diets concerning cardiovascular disease, body mass index, type 2 diabetes, certain types of cancer, and all-cause mortality (American Dietetic Association 2009; Fraser 2009). These comparative benefits appear also to apply to low-carbohydrate plant-based diets versus low-carbohydrate omnivorous diets (Knight 2011).

Sixth, the underlying logic of Paleolithic nutrition may involve some fallacies. It is not unreasonable to think that the ideal human diet will depend on the nature and limitations of our physiology and furthermore that the nature and limitations of our physiology will in turn depend on the environmental context in which we evolved. However, proponents of Paleolithic nutrition often talk of the diet that humans were “designed” or “meant” to eat (see, e.g., Cordain 2002). This argument seems to confuse evolution with teleology. Evolution does not work towards ideal ends. Certain phenotypic traits and behaviors will be more conducive to survival and reproduction than others, but an organism may survive and reproduce without flourishing; and what is conducive or necessary to survival and reproduction will change with context.

Notwithstanding associated risks, animal protein can be a good source of both macro- and micronutrients, and in an ancestral environment where certain micronutrients such as vitamin B-12 or polyunsaturated fatty acids (PUFAs) were not abundant, animal protein may have helped to protect against risks of nutrient deficiency or poor cognitive development (Finch and Stanford 2004). However, the fact that animal protein is a good source of nutrition in an environment of relative nutrient scarcity does not mean that it is a necessary or ideal source of nutrition in an environment where key nutrients are otherwise obtainable.

The so-called meat-adaptive genes also highlight the importance of environment in determining adaptive value. Meat consumption in the ancestral environment posed risks of infectious disease and hypercholesterolemia. Some evolutionary biologists have proposed that humans evolved certain genes, such as the genes encoding Lipoproteins and Apolipoproteins, to better deal with these risks. For example, the *ApoE4* allele increases inflammatory responses and is thought to have been protective against infectious food-borne illnesses. However, this gene also predisposes persons to certain degenerative diseases later in life, including Alzheimer's disease and cardiovascular disease (Finch and Stanford 2004). Because the average human lifespan in the ancestral environment was much shorter than we presently enjoy in developed countries, such predispositions to degenerative disease would not have been a significant issue in the ancestral environment, though they are certainly an issue now. Furthermore, now that we have easier means of controlling food-borne illness (through safer production and knowledge about appropriate preparation and cooking), the benefit that *ApoE4* provided in the ancestral environment no longer seems as relevant.

Other versions of these genes, which evolved later, are thought to have promoted humans' development of larger cranial capacity and longer lifespan than other species, by enabling the more efficient binding and transport of animal fats (Finch and Stanford 2004). Some commentators who highlight the importance of animal source

foods in the human diet point to their "very important role in the evolution of our species" (Popkin 2009). However, the fact that animal source foods played an important role in human evolution, even if accepted as true, does not imply that the consumption of animal products is nutritionally ideal *now*. The genetic adaptations in question have already evolved – humans already have these genes, regardless of what dietary pattern they follow – and furthermore, humans cannot direct their own evolution. There is no reason to expect that the continued consumption of large amounts of animal protein will somehow result in further adaptations that are beneficial to human health or development.

Acceptable Risk and Risk-Potential Benefit Judgments

Though the assessment of nutritional risk associated with plant-based diets may involve contestable value judgments, it is nevertheless true that plant-based diets are associated with *some* risks. Since plant-based diets are also associated with potential benefits as compared to omnivorous diets, i.e., since omnivorous diets are also associated with risks, an ultimate judgment of nutritional adequacy or favorability for each dietary pattern must take into account both risks and potential benefits. These risks and potential benefits should be assessed without bias, but even when bias is absent the resulting judgments are still evaluative in the sense of involving prudential judgments about the goodness or badness of certain outcomes, the magnitude of respective risks and potential benefits, and thresholds for when risks should be considered acceptable. The questions of when dietary risks are acceptable, or when potential benefit outweighs risk, are beyond the scope of this entry. However, it should be emphasized that establishing that plant-based diets carry certain risks shows neither that such diets are not nutritionally adequate nor that plant-based diets are adequate but compare unfavorably to omnivorous diets. Given that appropriately planned plant-based diets can meet all nutritional needs *and* that such diets show health benefits as

compared to omnivorous diets, it might be asserted that appropriately planned plant-based diets have a favorable risk-potential benefit profile as compared to appropriately planned omnivorous diets in the ideal.

However, this conclusion may be premature, since the omnivorous diets used in comparisons may need to be differentiated more in terms of the type and amount of animal products consumed. Furthermore, as concerns certain risks and benefits, additional data will prove helpful, e.g., as concerns the relationship between ferritin and cardiovascular disease or the significance of low serum ferritin. Moreover, it may be useful to assess not only the comparative risk-benefit profile of adequately planned diets but also the risk-benefit profile of plant-based and omnivorous diets as they tend to be consumed in less than ideal circumstances. At present, these are open questions.

Summary

Discussions about the nutritional adequacy of plant-based diets often seem to presuppose certain framing assumptions or value judgments. These concern the following: (1) the level of scrutiny of the risks of plant-based diets as compared to the risks of omnivorous diets; (2) framing assumptions in the way plant-based diets are defined; (3) value judgments in the way dietary risk is defined, for example, as concerns bioavailability, serum biochemical markers, or relative versus absolute risk; (4) value judgments about what is natural being good, or about the ideal nature of ancestral dietary patterns; and (5) value judgments about acceptable risk and overall risk-potential benefit profiles. It is important to be aware of these value judgments, since they condition the nutritional assessment of plant-based diets. Furthermore, the discussion here suggests that in many cases, value judgments or framing assumptions involved in the nutritional assessment of plant-based diets may be contestable and may explicitly or implicitly give the impression that such diets are riskier than they actually are.

Introduction

Plato (429–347 BC) is one of the greatest literary and philosophic minds of the Western intellectual tradition. His wide-ranging philosophic legacy includes foundational contributions to the fields of ethics, psychology, political science, aesthetics, educational theory, epistemology, and metaphysics. In an often-quoted statement regarding his philosophic significance, Alfred North Whitehead writes, “The safest general characterization of the European philosophical tradition is that it consists of a series of footnotes to Plato.” In light of Whitehead’s claim, one should expect that there are significant contributions to the newly emerging field of the philosophy of food to be found in Plato’s writings. A summary of these contributions, which will be discussed in this entry, includes the problem of gluttony and the correlate virtue of moderation, the diet of the ideal city, and the harmonious order of the three parts of the soul (appetitive, spirited, and rational).

Interpreting Plato's Work

Plato's unique writing style presents the reader with some of the most engaging works in the history of philosophy, as well as some of the most difficult to interpret. His surviving works include 36 dialogues and 13 letters. There is ongoing scholarly debate whether some of these (especially the letters) may be erroneously attributed to him; that said, scholars are in general agreement about a core list of dialogues as being authentic in light of their stylistic and substantive consistency. The discussion that follows will primarily be focused on Plato's *Republic*, *Gorgias*, and *Protagoras* though there are relevant ideas regarding food ethics that run throughout his works. In particular, the dialogue *Charmides* is especially relevant insofar as it is devoted to an investigation of the virtue of moderation. The references to Plato's works in this entry, as well as in most translations and secondary works about Plato, will be to the Stephanus line numbers rather than to page numbers to facilitate finding a precise passage across different editions.

Unlike other intellectual figures, Plato presents his ideas in dramatic dialogues, whose literary form poses several problems in their interpretation (see Klein (1965) and Rutherford (2000) for a full account of what is entailed in interpreting Plato dramatically). Some of the problems inherent in interpreting the Platonic dialogue include situating arguments within the dramatic context, interpreting the use of literary devices (irony, character types, myth, and allegory), and assessing the ultimate status of provisional arguments that are either affirmed or rejected in the course of the dialogue. The tendency of older Platonic scholarship was to disregard the literary aspect of the dialogue in order to distill definitive arguments that could be attributed to Plato. In a provocative passage from one of the more trustworthy letters, Plato cautions against this tendency: "No treatise by Plato exists or will exist, but those which now bear his name belong to a Socrates become fair and young" (Plato 1929, 2.314c). Plato is suggesting that if there is a philosophy to be attributed to him, one should pay careful attention to the argument proffered by

Socrates; however, there remain several problems with either positing that Plato is simply writing down the ideas of his teacher or that the Socrates who appears in the dialogues is Plato's mouthpiece. Since Socrates wrote nothing, it is impossible to untangle his ideas from those advanced by Plato, though the artistry and philosophic rigor of the Platonic dialogues attest to Plato being more than a disciple of his teacher regardless of the extent to which he was influenced by him. Although Socrates is the principle and most convincing speaker in the majority of the dialogues, several of Plato's most important dialogues (*Sophist*, *Statesman*, and *Laws*) feature principle speakers other than Socrates. Additionally, one must consider the philosophic merits of the arguments proffered by the interlocutors even if these are on the surface rejected. Recent Platonic scholarship has become more sensitive to interpreting his ideas in light of these dramatic and literary concerns. This caution is particularly valuable in an area of inquiry like the philosophy of food that attempts to formulate Plato's contributions to this narrow subject divorced from the larger philosophic project. In this entry, arguments will be attributed to the specific character (Socrates, Callicles, and Glaucon) who forwards them and will only be attributed to Plato when it is warranted by the dialogue read as a whole.

The Problem of Gluttony

While modern culture may regard gluttony merely as a health issue, Plato treats the malady as a central concern throughout his works with widespread implications for his ideas on ethics, psychology, and epistemology. For Plato, individuals whose souls are primarily directed to appeasing their appetites for food, drink, and other bodily pleasures suffer from disordered souls that are incapable of apprehending truth as illuminated by the good and thus are hindered from realizing their own best interests. The problem is epitomized in the famous cave allegory from the *Republic*. Plato's Socrates offers a ruthless diagnosis of the human condition through an analogy to prisoners unaware of their own enslavement:

“Picture men dwelling in a sort of subterranean cavern with a long entrance open to the light on its entire width. Conceive them as having their legs and necks fettered from childhood, so that they remain in the same spot, able to look forward only, and prevented by the fetters from turning their heads” (Plato 1969, p. 514a–b). Just after recounting the story, Socrates provides an interpretation of the symbolism of the chains that bind the prisoner:

Observe then that this part of such a soul, if it had been hammered from childhood, and had thus been struck free of the leaden weights, so to speak, of our birth and becoming, which attaching themselves to it by food and similar pleasures and gluttonies turn downwards the vision of the soul – If, I say, freed from these, it had suffered a conversion towards the things that are real and true, that same faculty of the same men would have been most keen in its vision of the higher things, just as it is for the things toward which it is now turned. (Plato 1969, p. 519a–b)

The following conclusions (which will subsequently be discussed) can be drawn from this passage: (1) Plato considers gluttony or intemperance to be such a pervasive condition that it typifies most men’s souls, (2) the overweening desire for pleasure prevents individuals from apprehending the rational world of ideas, and (3) there is a complementary passion for knowledge that is accessible to an individual that is able to master his or her appetites for bodily pleasure.

Why would Plato believe that the problem of intemperance is so pervasive as is suggested by the cave allegory when modern psychology regards the food, drug, or sex addict as manifesting extreme behaviors rather than the norm? Although the representation of the gluttons as chained prisoners suggests that the individual is largely passive in the acculturation process by which this psychological disposition has been habituated, Plato affirms that people are rational creatures who intentionally pursue what they believe to be in their best interests. The glutton is thus not intentionally engaging in self-destructive behavior, since as Socrates affirms in *Protagoras*: “no one willingly goes after evil or what he thinks to be evil; it is not in human nature” [...] (Plato 1924, p. 358c–d). If people are rationally seeking their own good, then why would

gluttons or other kinds of addicts indulge their appetites to the point of endangering their health?

Since Plato assumes that humans are rational creatures, he concludes that self-destructive behavior must arise out of a misperception of the effects of these actions. Most people, in fact, are mistaken about their best interest by overvaluing the pleasure they will derive from immediate gratification without regarding the long-term consequences of their actions. Socrates proposes in *Protagoras* that this problem could be rectified if individuals employed a more objective system for reckoning pleasures and pains than what seems good in the moment:

Is it not the latter [appearances] that leads us astray, as we saw, and many a time causes us to take things topsy-turvy and to have to change our minds both in our conduct and in our choice of great or small? Whereas the art of measurement would have made this appearance ineffective, and by showing us the truth would have brought our soul into the repose of abiding by the truth, and so would have saved our life. (Plato 1924, p. 356d–e)

Socrates’ idea of employing an objective system to weigh the long-term costs and benefits of a desire shows the obvious flaw in the glutton’s rationale. Since individuals innately seek their own good, they would not value the immediate pleasure they derive from something if they were able to weigh this against its potentially fatal side effects. Socrates illustrates the point in *Hipparchus* by noting that a dinner of poison, no matter how delectable it may be, is not nourishment: Do you include [as an example of profiting from something] a case where, after enjoying a banquet at which one has had much good cheer without any expense, one acquires an illness? (Plato 1927, p. 231b). Although people believe that they are the best judge of themselves, Socrates argues in several passages that people would need the knowledge of a physician to know with certainty that a food was actually nutritious (Plato 1924, p. 313d; 1925, p. 464d).

Although Plato explains gluttony as resulting from ignorance, he recognizes the rationale that overindulgent individuals employ to justify their lifestyles. In the dialogue *Gorgias*, Callicles argues that the man who is able to satisfy his desires is far from a slavish couch potato – an exemplar of manly

virtue and more self-actualized than the common man: “natural fairness and justice, I tell you now quite frankly, is this – that he who would live rightly should let his desires be as strong as possible and not chasten them, and should be able to minister to them when they are at their height by reason of his manliness and intelligence, and satisfy each appetite in turn with what it desires” (Plato 1925, pp. 491e–492a). Callicles goes on to claim that temperance is only promoted as a virtue by those weak individuals who are without the resources and power to fulfill their desires (Plato 1925, p. 492a–b). Nobody would, according to Callicles, restrict his or her desires when he or she had the ability to indulge them without restraint.

Socrates attempts to discredit Callicles’ ennobling of the unbridled pursuit of pleasure by arguing that hedonists’ insatiable desires actually cause them more pain than individuals who are able to satiate their desires. In a poetic image in which the various desires are compared to different liquids which the individual is burdened with the task of filling up in their respective jars, Socrates contrasts the temperate individual with the gluttonous and licentious: “One man, when he has taken his fill, neither draws off any more nor troubles himself a jot, but remains at ease on that score; whilst the other finds, like his fellow, that the sources are possible indeed, though difficult, but his vessels are leaky and decayed, and he is compelled to fill them constantly, all night and day, or else suffer extreme distress” (Plato 1925, pp. 493e–494a). Although Callicles retorts that individuals who are constantly filling their jars will derive greater pleasure through the continuous activity of inflow, Socrates notes that this sense of pleasure is only achieved by the simultaneous feelings of pain caused by the deprived state of hunger or thirst: “you say one enjoys oneself, though in pain at the same moment, when you say one drinks when one is thirsty?” (Plato 1925, p. 496e). In a similar discussion in *Republic*, Socrates clarifies that the pleasures and pains associated with the appetites are only a result of their oscillation from the opposing state; consumption of food regardless how delectable it may be is not as pleasurable when one is not hungry. He then contrasts the ephemeral quality of bodily pleasure

with the pleasures to be derived from filling the soul with unwavering knowledge: “If, then, to be filled with what befits nature is pleasure, then that which is more really filled with real things would more really and truly cause us to enjoy a true pleasure, while that which partakes of the less truly existent would be less truly and surely filled and would partake of a less trustworthy and less true pleasure” (Plato 1969, p. 585d–e). In several passages, Socrates attempts to redirect the desire for bodily pleasure into a desire for learning and truth.

Socrates’ most ruthless condemnation of the glutton comes in his examination of the individual who is diagnosed as suffering from a tyrannical disposition of the soul. In the previously examined passages, gluttonous individuals are considered only insofar as they torture their own souls by engaging in a ceaseless pursuit of desire. In contrast, the over indulgence in food and drink in tyrannical souls acts as a gateway to their complete disregard for all decency in an unabandoned pursuit of illicit activities:

When under the tyranny of his ruling passion, he is continuously and in waking hours what he rarely became in sleep, and he will refrain from no atrocity of murder nor from any food or deed, but the passion that dwells in him as a tyrant will live in utmost anarchy and lawlessness, and, since it is itself sole autocrat, will urge the polity, so to speak, of him in whom it dwells to dare anything and everything in order to find support for himself and the hubbub of his henchmen, in part introduced from outside by evil associations, and in part released and liberated within by the same habits of life as his. (Plato 1969, pp. 574e–575a)

Although this might at first seem to be an extreme description of an individual who is as depraved as the one described by Socrates, Plato is actually providing a subtle understanding of how addiction afflicts the soul in such a manner as to subvert all respect for common decency.

The Diet in the Ideal City

In the previous section, Plato’s treatment of the psychological and ethical implications of the vice of gluttony was examined. The core argument of

Plato's *Republic* will now be examined to understand the complementary virtues of temperance and justice. Since the inner workings of the soul resist direct apprehension, Socrates proposes that he and his discussion partners investigate the order and disorder of various political regimes under the notion that an individual and a state are similarly constituted. The subtleties of normal and abnormal psychology are thus made manifest by comparison with an ideal regime and several deviant regimes that correspond to different psychological types. The diet of the citizens in the various regimes that are proposed will turn out to be a crucial part of the overall discussion.

Socrates begins his project of political theorizing by imagining a city that is devised solely to satisfy the conditions of utmost necessity. He designates this city as healthy since the citizens in it will only consume those goods that are necessary to preserve their lives. With particular focus on their diet, Socrates describes the healthy city in the following manner:

First of all, then, let us consider what will be the manner of life of men thus provided. Will they not make bread and wine and garments and shoes? And they will build themselves houses and carry on their work in summer for the most part unclad and unshod and in winter clothed and shod sufficiently? And for their nourishment they will provide meal from their barley and flour from their wheat, and kneading and cooking these they will serve noble cakes and loaves on some arrangement of reeds or clean leaves, and, reclined on rustic beds strewn with bryony and myrtle, they will feast with their children, drinking of their wine thereto, garlanded and singing hymns to the gods in pleasant fellowship, not begetting offspring beyond their means lest they fall into poverty or war? (Plato 1969, p. 372a–c).

As Socrates notes at 373c, this first city is completely vegetarian (Dombrowski 1984). In one of the most famous lines of the entire dialogue, Glaucon vigorously protests against the diet that Socrates proposes for the city as being too bland: “No relishes apparently, for the men you describe as feasting” (Plato 1969, p. 372c). Socrates ironically responds to Glaucon's demand for more appetizing and indulgent cuisine with

relishes and desserts that are just as nutritious as the city's staple diet of barley cakes:

I forgot that they will also have relishes – salt, of course, and olives and cheese and onions and greens, the sort of things they boil in the country, they will boil up together. But for dessert we will serve them figs and chickpeas and beans, and they will toast myrtle-berries and acorns before the fire, washing them down with moderate potations and so, living in peace and health, they will probably die in old age and hand on a like life to their offspring. (Plato 1969, p. 372c–d)

Interestingly, Socrates seems not only to identify the citizens' diet as being responsible for their physical health but also the city's political stability.

Socrates refers to this first city as healthy and true; however, its ultimate significance in the argument is disputed by both readers and scholars alike. Many find in the description a Utopian ideal of individuals living in harmony with nature and cooperatively sharing in a mutually beneficial community in which all the citizens' needs are met even if this be at a minimal standard of living. McKeen (2004) notes that this sort of harmonious living without any formal political institutions is an impossible ideal. In contrast, Bloom (1991, p. 346) notes that the absence of philosophy from the city makes it ultimately undesirable as a Platonic ideal. Finally, Reeve (1988, pp. 176–178) notes that the city does not share its consumables in the manner of a family or a commune but rather is an association of self-interested moneymakers who exchange their wares in the marketplace solely for their own advantage.

Glaucon certainly does not regard the healthy city to be any sort of ideal (Bloom 1991, p. 346; Burnyeat 1999). He is not in the least humored by Socrates supplementing their diet with nutritious desserts and denounces the entire city on account of its cuisine as beneath what is fitting for humans: “If you were founding a city of pigs, Socrates, what other fodder than this would you provide?” (Plato 1969, p. 372d). Like Callicles, Glaucon identifies consumables as signifiers of one's social status and thus is genuinely offended that a city that is supposed to exemplify virtue would have its citizens eating nuts and berries while lying in a pile of leaves. His original request for relishes is really the demand for the comforts of civilized living: “They must recline on couches, I presume,

if they are not to be uncomfortable, and dine from tables and have made dishes and sweetmeats such as are now in use” (Plato 1969, p. 372d–e). This time Socrates does indulge Glaucon’s request as he introduces luxuries into the first city that transform it into a second regime known as the feverish city: “For there are some, it appears, who will not be contented with this sort of fare or with this way of life; but couches will have to be added thereto and tables and other furniture, yes, and relishes and myrrh and incense and girls and cakes – all sorts of all of them” (Plato 1969, p. 373a). Recognizing that desire without restraint will be insatiable, Socrates continues to introduce more and more luxury goods into the feverish city culminating in the declaration that they will now need physicians to attend to the diseases that will inevitably arise from the city’s unhealthy diet and, even more troubling, they will now need warriors to wage war on their neighbors in order to pillage their neighbor’s resources and expand their own borders (Plato 1969, p. 373d–e).

The introduction of the warrior class and their ultimate assumption of a ruling position within the city will transform the feverish city into a third regime, which represents the ideal for which Socrates was seeking. Socrates establishes order within this city by enacting a three-class structure consisting of rulers, auxiliaries, and craftsmen that each has a role in contributing to the overall harmony of the city. The immoderate and insatiable citizens of the feverish city will now be restrained by laws that are imposed by the philosopher-kings and enforced by the spirited auxiliaries. This three-class structure reveals the analogous three parts of the soul: “One part, we say, is that with which a man learns, one is that with which he feels anger. But the third part, owing to its manifold forms, we could not easily designate by any one distinctive name, but gave it the name of its chief and strongest element; for we called it the appetitive part because of the intensity of its appetites concerned with food and drink and love and their accompaniments, and likewise the money-loving part, because money is the chief instrument for the gratification of such desires” (Plato 1969, pp. 580e–581a). As was evident in the feverish city, the appetites are incapable of discerning

one’s best interest since they know no restraint and only seek to pursue additional pleasure. This condition allows individuals to be easily seduced in choosing the culinary artist’s delicacies even when they are in need of the physician’s medicine. Internal harmony is only achieved when individuals are able to regulate their appetites by the rule of reason aided by the spirited faculty (Plato 1969, pp. 443d–444e).

Although the healthy city’s vegetarian diet and moderate lifestyle may, at first glance, seem to be the most appealing regime presented in the *Republic*, especially when compared with the immoderate and bellicose feverish city, the true order of the soul only is revealed by the third regime in which the unhealthy excesses of the second regimes are purged.

Summary

As may be seen in this entry, the vice of gluttony and its complementary virtue of temperance are featured prominently in Plato’s writings. Individuals that are afflicted by gluttony not only suffer physical harm as a result of their diets and lifestyles but also from a psychic disorder that is further responsible for instigating illicit behaviors and ultimately a complete disregard for all ethical standards. As long as the individual remains afflicted by a gluttonous soul, he or she is prevented from apprehending the true reality and thus hindered from realizing his or her own best interest. Although Plato considers the physical, psychological, and ethical merits of a vegetarian diet, he ultimately endorses the city that is ruled by philosopher-kings and not the healthy city as his ideal polity. Moreover, it is through the class structure of this third regime that the three parts of the soul are revealed. Just as the city achieves justice and moderation through the rule of reason, so too will the individual achieve psychic harmony when his or her reasoning faculty rules over his or her appetites with the aid of the spirited part. In the final analysis, Plato is a harsh critic of the ill effects of immoderation; however, rather than simply restraining desire, he seeks to redirect it to a salutary passion for the love of wisdom.

Introduction

Agronomy, in the Anglophone tradition, is usually understood as the application to crop production of knowledge and technology developed from the plant and soil sciences. Through both formal and informal research and practice, new agronomic knowledge and technology are created that can be used to address “technical” problems within existing production systems, develop new systems, and/or to further specific social, political, economic, technical, and/or commercial objectives. Any aspect of this process may be contested, from the identification of a problem or the configuration and performance of a new technology or system through to the vision (implicit or explicit) of a desirable future world that underpins it. With **politics** understood broadly as social relations involving authority or power, the term **political agronomy** refers to the study of relationships and processes which link political, economic, and social forces and factors to the creation and use of agronomic knowledge and technology. Political agronomy studies differ from other studies of agricultural science and technical change within agriculture by problematizing the creation and use of agronomic knowledge and technology in terms of asymmetric power relations, contestation, and struggle. Used in this way, political agronomy relates to and draws from the fields of science and technology studies (STS) (Sismondo 2012) and political ecology (Robbins 2011).

Following Sumberg et al. (2012b), while the creation and use of agronomic knowledge and technology are by their very nature “political,” beginning in the mid-1970s, what had been a relatively stable context for agronomy and agronomists began to change. Over the course of the following three decades, this context changed dramatically, making the political nature of agronomy more apparent. The new context for agronomic research can be understood in terms of change in three closely related elements: society (changing ideology, new roles, new actors, new spaces), agriculture and the associated food economy (increasing scale, global consolidation, new systems of regulation), and agricultural science

(new foci, new tools, change in where and by whom it is carried out and who it is funded by). For much of the twentieth century in Europe and North America, agronomy functioned as a technical discipline focused on the critically important but largely practical matter of improving crop production. In this context, but particularly following the growth of state planning and economic management in the 1930s, politics around agronomy and agronomic research was dominated by the state, which set policy priorities, funded research, and promoted the uptake of resulting technologies. With the state as “principal” and research agronomists in universities and state-funded institutions as “agents,” there was a strong unity of purpose, with modernization at its core, between the state, the discipline of agronomy, and farming communities. This unity of purpose and the practical, problem-solving orientation of agronomy meant that as a discipline it experienced little of the heated debate that shook some other academic fields to their cores (cf. Harwood 2013). However, the position of agronomy began to change with the rise of the neoliberal agenda and emergence of the environmental and participation movements in the 1970s.

A faith in the role of “free markets” and a desire to “shrink the state,” combined with new intellectual property regimes and emergent biotechnologies, opened the way for a much expanded role for private capital in agricultural research and technology development and promotion. At about the same time, in some quarters, there was increasing concern about the environmental impacts of modern farming practices, while in others, the notion gained ground that in the developing world, poor farmers were not benefiting from – or were even being harmed by – new agricultural technology, leading to calls for more “participatory” and empowering approaches to research. Taken together, these changes represented a fundamental shift in the context within which agronomic research was prioritized, funded, managed, implemented, and evaluated. With agronomists still acting as agents (although now working in a wider array of organizational and institutional settings), the

principals had become more numerous and their institutional imperatives, agendas, and motivations more diverse. An unintended consequence of this restructuring of agronomic research has been the opening up of new spaces for contestation both within the discipline and about the knowledge and technology it produces. While these changes and their effects have been evident to varying degrees in different settings, there is enough of a common thread to warrant systematic study. Active and wide-ranging intradisciplinary and interdisciplinary debate and public contestation and activism around agricultural technology have coincided with renewed concern about the ability of agriculture to deliver both global food security and natural resource sustainability. Political agronomy studies are more relevant now than ever.

Scholarship on agriculture and food policy contains an important strand that explores the political economy aspects of agricultural research in specific national contexts and in relation to specific crops, technologies, and global research initiatives such as the centers of the Consultative Group on International Agricultural Research (CGIAR). Political agronomy draws from this literature but highlights both the rapidly changing social, economic, and technological contexts within which agronomic research takes place and the fact that these changing contexts have significantly reduced the state's ability to use traditional policy instruments to affect the direction and rate of technical change within agriculture. Thus it is the changing political economies of agronomic research, their interaction and coevolution over time and space, and the associated debates, contestations, and struggles that "frame" political agronomy analysis. From a political agronomy perspective, the questions of interest relate to the drivers of processes of framing and reframing; the actors and relationships involved; and the impacts of different framings and narratives on the conception, practice, and presentation of agronomic research and what it can deliver.

In the remainder of this entry, this argument is developed using examples of knowledge and technology developed through agronomic research.

Knowledge and Technology at the Center of Political Agronomy

Political agronomy analysis necessarily focuses on and revolves around efforts to generate and promote the use of new agronomic knowledge and technology. While any number of different schemes could be used to classify research, innovation, and technical change within agriculture, cases of technology generation can be assigned to two main groups. The first, encompassing perhaps the bulk of "everyday agronomic research," includes the countless examples of incremental innovation, each meant to address a specific "technical" problem within a given production system or context or to provide the user ("farmer/producer") with some marginal advantage. New crop varieties, new pest control products or strategies, and new fertilizer application rates or methods might typify this kind of incremental innovation. By definition, there is little that is radical in these examples: rather, they are about maintaining, stabilizing, or incrementally improving existing systems. In agricultural economies where innovation is largely in the hands of private sector actors (e.g., seed, chemical and fertilizer companies), the dynamic of incremental innovation is driven in large part by a desire to maintain or increase market share and profit margins. Contestation around examples in this first group tends to be limited; focused on technical performance, benefit-cost, etc.; and has limited public profile.

In contrast, in the second group are examples of the generation and promotion of agronomic knowledge and technology that are more radical and transformative. Here the direction of agronomic research is set by an objective of transforming the social, political, economic, technical, and/or commercial orders and is underpinned by both an analysis of "problems" or "constraints" and a vision of a desirable future which might encompass either a continuation of existing trends toward increasingly mechanized farming or a radical break toward smaller-scale "postindustrial" agriculture (Woodhouse 2010). Examples in this transformational group include the agronomic research that facilitated the mechanization of the California horticulture industry (Hightower

1972), the Green Revolution approach to the modernization of smallholder farming, the organic and agroecological farming movements, and the Millennium Villages program and the Sasakawa Global 2000 program in Africa. In these examples, agronomic research is used as a direct instrument of either government policy or the interests of other powerful (and sometimes less powerful) actors. The research agronomist may still work on varieties, fertilizer, soil management, etc. but perhaps even less constrained by the “real-world” limits faced by the current population of farmers. With examples in the second group, the potential for contestation is greater, including the analysis of the problem, its causes, and associated outcomes; the vision of the future agrarian society they are seeking to create, including expectations of who wins and who loses from the proposed change; the technical performance of the new technology or system; and the issues associated with the other policies, measures, and institutions needed to support it. Contestation and public activism may coalesce around a number of social, political, economic, and environmental concerns (Table 1), many of which are outside the traditional disciplinary bounds of agronomy. For example, the protracted debates about the poverty, labor, and equity effects of the Green Revolution in Asia in the 1970s and 1980s primarily involved social scientists and economists (Orr 2012), not agronomists or plant breeders, and had little profile in mainstream agronomy journals. In contrast, recent debates about GM varieties, conservation agriculture (CA), and the System of Rice Intensification (SRI) are much more in evidence in these same agronomy journals.

Both incremental and transformative innovation may be associated with unforeseen and unintended consequences, and both the possibility and reality of these may change the focus, nature, and/or intensity of contestation. This highlights the interplay of different understandings of and approaches to risk, uncertainty, and ambiguity in the politics around agricultural technology and the associated dynamics of contestation. Debates and activism around the potential effects of GM crop varieties on human health and weed populations illustrate how these different understandings can

be used tactically to affect both the public mood and regulatory outcomes.

Another widely used tactic in contestation around agricultural technology involves framing and reframing, based on the observation that in some situations, small changes “in the presentation of an issue or an event produce (sometimes large) changes of opinion” (Chong and Druckman 2007, p. 104). For example, a technology such as GM crop varieties can be framed as an incremental innovation (simply the latest in a long line of improved varieties) or as “technology for the poor” (Glover 2010) or be reframed as a transformative technology in either a positive (allowing significant reductions in pesticide application or improved nutrient content through “biofortification”) or negative (facilitating even greater concentration of corporate control over key agricultural and biological resources) sense. Similarly, an apparently innocuous incremental innovation can be reframed as a shortsighted “technical fix” because it neither acknowledges nor addresses what the reframer considers the underlying structural issue, while potentially

transformative innovations such as organic agriculture are reframed as idealistic and impractical.

Closely related to the question of framing is another important dimension of the new politics of agronomic research and technology in the developing world – the heightened imperative to demonstrate impact and “value for money.” This imperative operates at many levels, from the individual research agronomist, program, and institute through to the research funding agencies (public, charitable, or private), development ministries, and so on. In addition, agricultural development actors, from local community groups and district-level extension services through to international NGOs and UN agencies, are under increasing pressure to justify their continued funding by demonstrating the success of their actions. The multiple and overlapping levels at which agronomists work, from experimental plots and farmer’s field to production systems and landscape, provide fertile ground for this element of the new politics of agronomic research. The stakes can be quickly raised – from “promising results” to the promise (or claim) of “impact at scale” – during which situated agronomic knowledge and technology become progressively “silvered” into the next universal technology bullet. The Internet and other media that are less constrained by the ethos of peer review are critical to the dynamic of “success making,” the act of proclaiming a particular project, program, innovation, technology, policy, or organization a success in a way that may shelter the claim from normal scrutiny and critical evaluation (Sumberg et al. 2012a).

To summarize, the building blocks of political agronomy analysis emerge from addressing questions in four related domains:

The agronomic problem being addressed: How is it framed, at what scale, and by whom? How high a priority is it, for whom, and in what situations? How are risk, uncertainty, and ambiguity understood and addressed, and by whom?

The agronomic solution being proposed: How is it framed, at what scale, and by whom? How effective it is, by what criteria, at what cost, for whom, and in what situations? What benefits

does it generate, for whom, and in what situations? How are risk, uncertainty, and ambiguity understood and addressed, and by whom?

The socioeconomic problem being addressed:

How is it framed, at what scale, and by whom? How high a priority is it, for whom, and in what situations? How are risk, uncertainty, and ambiguity understood and addressed, and by whom?

The socioeconomic solution being proposed:

How is it framed, at what scale, and by whom? How effective it is, by what criteria, at what cost, for whom, and in what situations? What benefits does it generate, for whom, and in what situations? How are risk, uncertainty, and ambiguity understood and addressed, and by whom?

These questions situate political agronomy studies firmly in time and space and in a social, political, and economic context, all of which are prerequisites for meaningful analysis of the relationships and processes linking political, economic, and social forces and factors to the creation and use of agronomic knowledge and science and technology.

Contemporary Examples

Three contemporary examples of agronomic technology – conservation agriculture (CA), GM crop varieties, and the System of Rice Intensification (SRI) – help to illustrate many of the elements discussed above. While these technologies have very different origins, address different problems, and are supported by different interest groups and coalitions, they have all been (and continue to be) the subject of heated debate and contestation both within agronomic research circles and beyond.

Conservation Agriculture (CA)

The technology of CA as promoted in the developing world is defined by (i) minimal soil disturbance or tillage, (ii) maintenance of soil cover through crop canopy and mulch, and (iii) crop rotation. Proponents claim that the CA is both productive and profitable and that its practice

brings economic, agronomic, environmental, and social benefits (Kassam and Brammer 2012). Increased levels of soil carbon, improved soil structure and in-soil water conservation are the most often cited agronomic benefits. Contestation focuses around the universality of these claims and the effects of differences in soil type, rainfall regime, farming system, mulch availability, planting method, weed control method, and fertilizer application on the presence, level, and variability of any benefits (Giller et al. 2009). Despite evidence of site and context specificity, the transformative potential of CA as the basis of sustainable, pro-poor agriculture everywhere is heavily promoted. It is framed as a technology that can stimulate increased investment on the part of poor farmers, especially in Africa, and result in much needed productivity gains. CA is increasingly being framed as the prime example of “climate-smart agriculture” (CSA), sustainably increasing productivity and resilience (adaptation) and reducing greenhouse gases (mitigation) while enhancing the achievement of national food security and development goals. The promotion of CA in Zimbabwe, with its links to national politics, the global political economy of development and humanitarian assistance, and Christian faith groups, provides the case for a particularly compelling political agronomy analysis (Andersson and Giller 2012).

GM Varieties

The technical debates surrounding the development and use of agricultural biotechnology, particularly genetically modified (GM) crop varieties, are reminiscent of debates around the Green Revolution. Proponents of GM crops tend to present them as a technical answer to the problem of global hunger, based on promises of increased productivity, lower input costs, and reduced environmental impact (Bruce 2012). The world’s food problem is framed mainly as a matter of supply, the solution to which is GM crops. Critics respond that on the ground GM crops often fail to live up to these promises. Further they raise the specter of crops that can be toxic, allergenic, or less nutritious than their natural counterparts; that can disrupt the ecosystem

through genetic drift to crop and weedy relatives; that can increase rather than reduce pesticide and herbicide use over the long term; and that can lead to herbicide-resistant weeds. Different understandings of evidence, risk, uncertainty, and ambiguity loom large in these debates. One key debate about the transformational potential of GM varieties revolves around their impacts on poverty, hunger, and the livelihoods of poor people. Some advocates have suggested that GM varieties could reinvigorate the stalled Green Revolution, reframed as a “Gene Revolution.” Critics charge that this vision overlooks the vital role that political and economic interests and allied institutions play in shaping the outcomes of technological change (see Glover 2010). In other words, delivering the pro-poor promise of biotechnology requires appropriate regulatory and governance procedures which are often lacking in many countries. Another major front in the contestation around GM varieties relates to the fears on the part of some concerning the dangers of even greater corporate control over key biological and livelihood resources such as seeds, thus linking resistance to GM crops to debates around globalization and “food sovereignty.”

System of Rice Intensification (SRI)

This technology is defined by its supporters to include the transplanting of single, very young, widely spaced seedlings; irrigation using limited amounts of water during the vegetative growth period, sometimes including short periods when the soil is allowed to dry; and careful control of weeds, ideally by disturbing the soil so as to increase aeration (Stoop et al. 2002). Application of substantial quantities of organic fertilizer is encouraged in order to stimulate microbial activity in the soil. Proponents of SRI suggest that it must be understood as a set of “principles” to be adapted to local conditions rather than a fixed technological package. The main lines of contestation have been around the very high yield levels claimed by some proponents, the physiological effects of different soil water regimes (flooding depth and cycles of wetting and drying) on soil and plant physiology, the validity of measurements of component effects when interactions

(synergies) are strong, and the real extent of the differences between SRI and the “best agricultural practices” developed and promoted through formal agricultural research (Glover 2011). The transformational potential of SRI has also been hotly contested in terms of, for example, the rate and extent of adoption by farmers and the power of populist science and “people’s movements” to deliver sustainable productivity gains among small-scale farmers more effectively than formal agricultural research institutions. From a political agronomy perspective, the SRI example turns around the contested nature and meaning of knowledge and evidence and the relevance of the Internet as a new site for mobilization and contestation.

Summary

Over the last 30 years, changes in the context within which agronomic research is prioritized, funded, managed, implemented, and evaluated have altered the nature of contestation about and around agronomic knowledge and technology. Because of the importance of agronomy and agronomic research in supporting productive and sustainable agricultural systems, systematic analysis of the implications of these changes – political agronomy studies – should now be given high priority.

The CA, GM crop variety, and SRI examples highlight an overriding imperative to claim universal applicability and the potential of “impact at scale.” This is at odds with the understanding of agronomy as a problem-oriented, “situated” science and accounts for the competing claims and much of the acrimony generated by these technologies. Can CA, GM varieties, SRI – or any other technology – provide a universally applicable solution to the problems of sustainable agricultural production? Centuries of agronomic knowledge accumulated through both practice and formal research refute any such suggestion. The challenge for political agronomy studies is to analyze the forces that are driving claims to universality, the actors and coalitions that are making and contesting these claims, and the implications

for agricultural producers, consumers, the environment, and the discipline of agronomy itself.

Introduction: What Is Political Consumerism?

The concept of political consumerism identifies instances when people evaluate and choose producers and products because they want to change ethically, environmentally, or politically objectionable institutional or market practices. Practices within political consumerism are informed by attitudes and values regarding broad issues of sustainable development that can even include beliefs about the responsibility of different actors involved in production and consumption and the role of government in using the market as an arena for politics (for interesting discussions on this, see Young 2006; Forno and Gunnarson 2010). Political consumerism can be practiced by individuals, civil society groups, and governmental, not-for-profit, and for-profit organizations. In different ways and for different reasons, political consumers understand producers and products as well as consumers and consumption as embedded in a complex social and normative context that has been called the “politics behind products” (Micheletti 2010). Research points to both self-interest (e.g., personal and family health) and other-oriented interests (e.g., climate change, social justice) as important explanations for the rise of political consumerism particularly for individuals and civil society. Governmental and corporate engagement in political consumerism remains understudied.

Four Forms of Political Consumerism

Scholars identify four basic forms of political consumerism that can be studied through different methods and empirical material. Perhaps the oldest form is boycotts (or negative shopping decisions), which are defined as deliberate or conscious choice not to purchase a commodity, brand, or even a good from a particular country. Some boycotts are well-organized activities that mobilize considerable numbers of consumers even cross-nationally into a particular cause. In certain cases, boycotts have a political effect on governmental politics and corporate policy, though it is

difficult to find good measures of effectiveness here (for more information on the strategies, success, and effectiveness of boycotts, see Friedman (1999) and Stolle and Micheletti 2013). Examples of influential boycotts are the decade-long Nestlé boycott against marketing infant formula in developing countries, which led to a new international agreement (Sikkink 1986) and later some corporate change; the green boycotts organized by environmental groups in the 1980s and 1990s that convinced many do-it-yourself and affordable furniture companies in the wood industry (e.g., Home Depot, IKEA) to reconsider how they procured the tropical wood sold in their stores (Cashore et al. 2004); the boycotts of Nike, Gap, and other global garment corporations now leading to certain corporate change and multi-stakeholder initiatives to help solve the labor problems in outsourced manufacturing (Stolle and Micheletti 2013); and the animal activist and green boycotts against McDonalds and Burger King to change their procurement policies on egg and chicken sourcing. Boycotts of South African goods (particularly fruit) were part of the global anti-apartheid movement (Seidman 2003). Today this boycott is a role model for the “Boycott Israel Today,” supported by some trade unions, churches, and countries, which focuses on products from territories occupied by Israel. The European union has even formulated guidelines on this matter (EU 2013; BBC News 2013; Guardian 2013).

Widespread boycotts target well-known and frequently purchased products and offer consumers suggestions about similar goods to replace them. Boycotting is, therefore, reliant on the availability of similar goods considered to be better for various reasons.

Buycott is the term used to identify the practice of deliberate conscious choices (positive shopping decisions) to purchase certain commodities over others, that is, those often considered more environmentally friendly, more ethical, or preferable for other political reasons. Buycotted goods might, for instance, be chosen because they are seen as reflecting better worker treatment (e.g., by shopping at ethical clothing companies or following advice offered by fairtrade labeling), more

healthy (e.g., organically labeled food), and generally better for the environment (e.g., ecolabels) (see more in next section).

Discursive political consumerism, the third form, does not directly involve such negative or positive shopping decisions but rather attempts at opinion formation and communicative actions expressing reflective and critical views held by individuals and/or collectivities on corporate policy, corporate practice, and consumer culture. Good examples here are antibranding and culture jamming, both of which criticize well-known brands and the commercialization of society in humorous ways (e.g., the animal activist Kentucky Fried Cruelty or Murder King campaign targeting the procurement policies of two well-known corporate brands) and performative events (e.g., anti-sweatshop fashion shows) because they illustrate how this form, through innovative measures, seeks to engage consumers, corporations, and political institutions in learning more and thinking reflectively about the politics behind well-known and attractive products (Sandlin 2007).

Lifestyle political consumerism, the final form, is a decision to use one's private life sphere to inform about and attempt to change established production and consumption practices. Its message is that practices in the private sphere have ramifications for politics. Vegans, freegans, and downsizers, for instance, argue that “the personal is the political” and attempt to adapt their lives to their political views on alternative consumption practices. Vegans commit to not consuming animals in any fashion and seek to purchase alternative goods not containing animal ingredients (Cherry 2010). Downsizers “live” their views by wanting and buying less, buying used goods, and choosing green and fairtrade products (Huneke 2005). Freegans are known for diving into dumpsters after food and other goods as part of their alternative food activism that criticizes agribusiness and conventional consumption practices.

The different forms of political consumerism can also be used in tandem, for instance when consumers are asked in holiday campaigning to boycott certain well-known chocolate brands, choose fairtrade or organic labeled chocolate

instead (boycott), and send messages to corporate headquarters about their choices (discursive action). Finally, emerging research is showing that social media is increasingly important in innovating political consumerism (e.g., carrotmobs) by facilitating the development of individualized political identification in settings other than the parliamentary and through social and other networks (cf. Calenda and Meijer 2011).

Surveys conducted in different Western countries and other research find that political consumerism is generally increasing as a practice among individuals, public and private institutions, and civic groups in different countries. But it appears that boycotting has gained most in importance. European survey data (see Stolle and Micheletti 2013) reports particularly high levels of boycotting in the Nordic countries, with boycotting showing some decline. In these surveys Sweden stands out as highest; about 56% of adult Swedes engage in boycotting and boycotting activities. These rises can be explained by civil society's heightened interest in using marketing campaigning for their cause and government's support for labeling schemes and use in its public procurements. Boycott political consumerism is now part of public procurement policy in many parts of the world and even promoted by major transnational corporations, which now have codes of conduct to help govern their relationships and transactions with their suppliers and sub-suppliers. Special ethical and environmental business initiatives in particularly the food and clothing industries have also appeared. Business interest in political consumerism is explained by the influence of the market campaigns run by various civic groups as well as corporate reasoning that profit, competitive advantage, and goodwill can be gained by contributing to the "boycott market" (for more further discussion see Stolle and Micheletti 2013).

What lies behind the rise in political consumerism is societal concern about safeguarding the environment worldwide, protecting global workers in various industries, and finding innovative strategies to establish new regulatory tools to make transnational corporations more accountable. The rises also reflect citizens' efforts to

engage in politics in new ways as well as their more self-interested concerns about finding healthy food and keeping harmful chemicals out of their own lives. Research (see Stolle and Micheletti 2013) finds that people with higher education and more political interest/activity and more women than men exhibit higher levels of political consumerism. The rich Swedish data (see Stolle and Micheletti 2013), allowing for deeper analysis, shows even that dissatisfaction with governmental performance on issues of the environment, human rights, and the war on poverty mobilize people into political consumerism but that, contrary to some theoretical expectations (e.g., on subpolitics), many political consumers (particularly those 30 years of age and older) have high trust in national representative political institutions. However, what makes political consumers different from "nonpolitical consumers" is that they are prepared to take more active responsibility for seeking explanations for societal developments and especially for showing consideration and concern for others. This final result indicates that political consumers (and especially younger ones) can be distinguished by concerns about nonreciprocal and more global aspects of politics and citizenship. These findings also underscore theoretical expectations that younger political consumers are more subpolitical and adopt a more political individualization orientation in that they seek to contribute to society in ways that better conform to their less state-centered and more private life-oriented world view (for references see www.sustainablecitizenship.com). Researches on environmental, religious, international humanitarian, and animal stewardship groups involved in political consumerism even show that civic groups also increasingly frame their campaigns in this fashion and, interestingly, focus more on the self-interest of consumers in their advocacy (for further information see Stolle and Micheletti 2013 and associated references).

Finally, while the concept of political consumerism is rather new, the four forms have been practiced for centuries. Boycotting and boycotting were, for example, part of the grand antislavery struggle in the 1600–1800s with people mobilized

into boycotts of cotton, tea, and sugar whose production involved slave labor and into buycotts of substitute so-called “slave-free” products. Boycotts also played a historic role in conflicts between Arabs and Jews in the Middle East, with scholars discussing them as “boycott wars.” Moreover, important areas of contemporary political consumerism, including fairtrade, organic food, and socially responsible investments, originated in religious activism from the 1700s and 1800s. Noteworthy is that political consumerism does not necessarily or automatically promote democracy and sustainable development. A telling example is how it became a weapon against Jewish merchants and the Jewish people in Europe in the 1930s and 1940s. This topic deserves much more research attention.

Political Consumerism, Information Systems, and Labeling

Political consumerism is highly reliant on the availability of information and alternative products on sale in the marketplace. In most cases this information and product availability is provided by labeling schemes. In recent decades, ethical and environmental labeling has emerged as a common and well-known way for increasingly mindful or conscious consumers to find “buycott” alternatives in the marketplace. Among the pioneering labeling schemes are the German Blue Angel ecolabel established in 1977 for everyday consumer products, the Nordic ecolabel (the Nordic Swan), the EU Ecolabel (the European ecoflower), and the US Green Seal. Today these schemes cover a broad range of product categories, including household chemicals, paper, paint, beauty care, office equipments, washing machines, toys, textiles, DVD players, computers, furniture, and so on. They also certify service providers such as hotels, restaurants, and cleaning services. Even organic food labeling has a long history, but grew in importance particularly since the 1980s when organic labeling schemes were introduced in a number of countries. Another example is Forest Stewardship Council (FSC), established in 1993 to set standards for

sustainable forestry as a way to govern the forestry commons. The FSC label can be found on primarily paper and furniture products and is an important label particularly for institutional consumers. The FSC covers a broad array of social, environmental, and economic aspects and is often mentioned as a pioneering case because it unites business actors with social and environmental NGOs. For social issues, fairtrade is the most well-known system, aiming at redistributing economic values along the mainstream commodity chain and establishing democratic governance structures for the benefit of small-scale and family-based agriculture in the global South.

Ethical, environmental, and even health labeling has become a commonly used consumer-oriented policy instrument. The Ecolabel Index (www.ecolabelindex.com) as of February 19, 2014 lists 446 labeling schemes, operating in 197 countries and in 25 industry sectors. Some ecolabeling schemes (e.g., the German Angel, Nordic Swan, and EU Ecolabel) cover multiple sectors, while others (e.g., Aquaculture Stewardship Council, Energy Star, Global Organic Textile Standards) are sector specific. Other types of consumer-oriented information tools include shopping guides, red lists, sustainability reporting, and fish wallet cards. Fish wallet cards (information fitting neatly in one’s pocketbook) use a “traffic light logic,” differentiating between Best, Ok, and Worst/Avoid choices that can be consulted for shopping decisions while also giving consumers the opportunity of retrieving further information about the fish, including recipes and nutritional information from websites. Currently carbon labeling is debated (Upham et al. 2011), with a key issue being if a labeling system should award the most climate-friendly products in relative terms within a product category or if entire product categories with high climate impact (e.g., beef) should be excluded completely.

What is labeling and why is it important? First, labeling is a market-based and consumer-oriented tool, founded on the standardization of principles and prescriptive criteria, and relying on symbolic differentiation (Boström and Klintman 2008; see also Gallestegui 2002; Horne 2009). Producers seeking to use the label for their goods must

meet the defined principles and criteria for a fixed period of time and for a given license fee. Labeling relies, at least implicit, on differentiation among products/production in terms of good/bad, friendly/unfriendly, green/gray, safe/risky, and sustainable/unsustainable. This property of symbolic differentiation is essential for understanding the attractiveness, dynamics, and controversies surrounding labeling schemes.

In some countries, consumer information on products is mandatory, such as declaration of contents (e.g., nutrition, GM contents, country of origin) and danger symbols (on cigarette packages). Mandatory labeling appears, according to Horne (2009), to be more prevalent for specific performance issues such as water- or energy-consuming devices. In the area of labeling most schemes rely on voluntary logic and positive information, however. It is less realistic that business would pay a license fee to the labeling and certification organization and voluntarily publish negative information on product packages.

Given the abundance and wide use of labeling schemes, an increasingly important concern is their credibility. Credibility issues concern, for example, how the labeling process is organized (its relative independence from the so-called first-party interests), the inclusion of relevant expertise and stakeholders view, and that judgment and decisions are based on a carefully selected set of principles and criteria which are generally reviewed and strengthened on a regular basis. The issue of credibility relates to a common distinction between first-party and third-party schemes. While the former refers to self-claims done by the producer or seller, the latter refers to an organized system independent of the producer, usually made up of a hybrid constellation of interests/stakeholders that may include the producer and seller. State actors may take part, either as one stakeholder among others or as the chief principal of the labeling scheme. The International Organization for Standardization [ISO] provides a definition and differentiation of environmental labeling schemes, the so-called 14,020 series. ISO distinguishes between *type 1* labels, a multi-attribute label

developed by a third party; *type 2* labels, a single-attribute label developed by the producer; and *type 3*, an ecolabel whose awarding is based on a full life-cycle assessment. It is important to remember that *type 3* labels, or any other kind of “environmental product declaration” scheme, are not labeling in the theoretical sense that emphasize *symbolic differentiation*. It is qualitatively different to disclose details and measures about environmental impact compared with adding the valuation that something can be defined as “good” or “better than.”

Why has labeling become quite widely used? Its simplicity is the simple answer. From a concerned consumer perspective, labeling can be a way to handle the information asymmetry existing between the producer and consumer on the environmental and social performance of production (Gallestegui 2002; Koos 2011). Labels seek and attempt to provide consumers with credible and concise information on these matters and even function as choice editing, that is, framing and narrowing the range of products available for the concerned consumer. The simplicity also has communicative advantages that link well to sustainable marketing efforts among producers and retailers as well as with the campaigning activities of consumer, environmental, and social NGOs. The latter groups also see an advantage in these *type 1* hybrid arrangements (see ISO definitions above) as they provide an organized forum to voice their concern in business matters (see Boström and Klintman 2008 for an extended discussion).

Labeling has had hugely varying market impact in different sectors: strong within the area of food, chemicals, energy (household products), and forest (paper) products and weaker (although growing) within the area of clothing, toys, and cosmetics. These variations concern both demand (harder to make people aware and motivated in relation to some types of products) and supply factors related to technological, organizational, economic, political, and geographical matters. How well labeling functions and whether or not it has a significant market impact varies considerably among countries. Scholars focus on a number of contextual factors to

explain these variations, among them are market structures including retailing structures, general income levels, civil society engagement, political cultures, level of state support, and type of trust relations in society (e.g., institutional or family based) (e.g., Cashore et al. 2004; Boström and Klintman 2008; Sønderskov and Daugbjerg 2011; Koos 2011).

Yet despite these variations, the general trend is growth in the number and scope of labeling schemes. From the consumer perspective, the problem is, however, that the multitude of labeling schemes, including even the presence of all kinds of eco-claims and green nature-like symbols on product packages, has been found to create a so-called “second-order” dilemma. Consumers not only need information about the content of products and which products are “good” or “bad” but also on which information providers (labeling scheme/organization/corporation) are credible and not. The issue of credibility or trust has, therefore, been of central importance in the labeling debate and literature (e.g., Boström and Klintman 2008; Sønderskov and Daugbjerg 2011). The use of “independent” third-party labeling schemes and other arrangements to assure credibility has not resulted in a closure of such debates but rather their accentuation. How are consumers to navigate in this jungle of labels and green symbols? Standardization of credible standardization is one solution. ISEAL Alliance, an umbrella organization of labeling and certification organizations, has established codes of good practice of setting sustainability standards and thereby tries to define and protect what a credible system of labeling consists of. Consumer navigational tools are another, e.g., ecolabel iPhone apps.

In addition to this credibility debate related to the abundance of green marketing and proliferation of “fake” labels, the labeling literature also discusses a number of other challenges associated with the development and functioning of labeling and certification system, including the balancing of input from science with other stakeholder demands (e.g., inclusion of consumer representation); balancing the need of simplicity (concise consumer information) and complexity (taking

into account all important sustainability matters and dimensions); considering the entire life-cycle and achieving traceability of raw material and products; the issue of labeling and barriers to trade, barriers to entry, and labeling as a disguised form of protectionism; balancing the need for universal principles and criteria with the need for sensitivity to local cultures, rules, and ecosystems; challenges in monitoring the compliance of labeling principles and criteria and requiring corrective measures; economies of scale in certification and labeling that result in difficulties for small- and medium-sized enterprises (SMEs) to accept the costs involved in the compliance of criteria (conversion costs, license fee, administrative costs, etc.); and the issue of how to keep a sharp political consumer identity of the labeling programs while facing mainstreaming (market growth) tendencies (examples from Gallestegui 2002; Boström and Klintman 2008; Horne 2009; Koos 2010). More research is necessary of all these challenges.

Summary: The Rise of Political Consumerism in Critical Perspective

Political consumerism in the four presented forms – boycotts, buycotts, discursive, and lifestyle – has risen dramatically as a consumer practice as well as a mechanism to provide information and alternative products and habits globally. Consumer demand has both relied upon the presence of labeling schemes and promoted their further development. Over time political consumerism has become a more mainstream activity. Yet this rise of political consumerism has met with some rather fundamental criticism. Among early supporters, the tendency to advocate boycott and lifestyle political consumerism for self-interest reasons and for mobilizing NGOs to employ emotional arguments is seen as going counter to the historical ideological current that focused on solidarity and the ethics for a small green planet. These critics fear that dedication and commitment to the cause of global solidarity and green living is threatened when it is turned into a shopping event. Even the rapid development of certification and

labeling has been criticized for similar reasons. Here the issue is co-optation of the values underlying the labeling initiatives by profit-seeking business. In the wittily entitled article “Unveiling the unveiling,” Guthman (2009) warns that the ethically labeled commodity can result in a kind of ethical fetishism, because of the many unveiled aspects of the labeling process. Labeling was initially established to reveal the unwanted social and environmental side effects of production and products invisible to consumers so that they could make more informed purchasing decisions. But if such critical side effects also remain in the products symbolically espoused as “good” at the same time as business makes new profits in this new “green” or “social justice” sector, then, she argues, it is valid to claim that consumers are cheated in a double sense. One possible path out of this new dilemma is the very same phenomena that gave rise to much contemporary political consumerism, namely, reflexivity (Boström and Klintman 2008). Here the argument is that even the promoters of political consumerism, including mobilizing NGOs, labeling schemes, and governments, should be more critical and reflective about their own and other actors’ knowledge claims. They will need to consider the consequences of using emotional arguments and appealing to self-interest for the goals that they want to reach through political consumerism and, more generally, whether it is truly possible to reach their goals by selling products.

Introduction

Pope Francis' much discussed papal encyclical, *Laudato Si (Praise Be): On Care for Our Common Home*, (Francis 2015) is addressed not just to Catholics or Christians but to the entire global community, to all of humanity. The encyclical is well known for its attention to climate change and to broader environmental questions related to the Creation and, as well, our response to those issues. But the encyclical also deals with matters of agriculture, raising many questions of agricultural ethics and values. This attention includes a discussion on GMOs and, as well, broader questions of large-scale industrial versus small-scale farming as a means to feed the world. As with all issues in the encyclical, questions of intergenerational equity and social justice, including a preferential option for the poor, and thereby questions of morality and moral choice, permeate the document. In all, there are 246 numbered paragraphs in the encyclical.

On GMOs

Following release of Pope Francis' encyclical, press releases from various sources claimed that Pope Francis had condemned the use of genetically modified organisms (GMOs), without leaving room for further discussion. A search of the

encyclical will not find any words of condemnation per se. The Pope, in fact, tells us that “(N)o conclusive proof exists that GM cereals may be harmful to human beings.” (*Laudato Si*, para. #134) However, then he adds the words “(T)here remain a number of significant difficulties which should not be underestimated.” (para. #134) A person reviewing his text describing these “difficulties” might well conclude that Pope Francis has, indeed, effectively condemned GMOs. How so?

He writes, “In many places, following the introduction of these crops, productive land is concentrated in the hands of a few owners due to the progressive disappearance of small producers who, as a consequence of the loss of the exploited lands, are obliged to withdraw from direct production.” (para. #134) The most vulnerable of these, he says, “become temporary laborers, and many rural workers end up moving to poverty-stricken areas.” He adds “we see an expansion of oligopolies for the production of cereals and other products needed for their cultivation... This dependency would be aggravated were the production of infertile seed to be considered. The effect would be to force farmers to purchase them from larger producers”. (para. #134) Thus, he is concerned about the direct and immediate human consequences of the adoption of transgenic (GMO) crops.

But Pope Francis is not unconcerned about the science. Given his academic background in chemistry, the Pope is very familiar with the need in science for honest, open, independent, and objectively based debate. He writes “A broad responsible scientific and social debate needs to take place, one capable of considering all the available information and of calling things by their name. It sometimes happens that complete information is not put on the table; a selection is made on the basis of particular interests, be they politico-economic or ideological.” (para. #135) We know that such a public debate has never occurred because the biotech industry has refused to open up its databases to verify whether or not transgenic crops are innocuous.

The Pope calls for needed discussions in which “all those directly or indirectly affected (farmers,

consumers, civil authorities, scientists, seed producers, people living near fumigated fields, and others) can make known their problems and concerns, and have access to adequate and reliable information in order to make decisions for the common good, present and future.” (para. #135) Francis thereby warns of the social, economic, legal, and ethical implications of transgenic crops. Thus, given the issues he has raised, it can be said that he has effectively condemned GMOs without using more direct language. And, since his own homeland, Argentina, is “the Latin American nation where GMOs have done the most to alter traditional agriculture,” (Godoy 2015) he is no stranger to the biological and the social effects of the introduction of transgenic (GMO) crops. Godoy tells us that soy, which is now 98 % transgenic, is now Argentina’s leading crop, a very recent development. Such extreme monoculture, high in its demand for both energy and sophisticated technology, is replacing local producers and fueling the concentration of land, leading to the many, both rural and urban, social problems of which the Pope speaks. And Argentina is the third largest transgenic crop producer in the world, after the United States and Brazil. Pope Francis, as Bishop and later as Cardinal Bergoglio of Buenos Aires, witnessed this reality for many years in his country and is likely basing his views significantly on his own life experience, which he himself has witnessed. His concern is with how the technology will impact the poor as well as all of God’s Creation. He writes “The expansion of these crops has the effect of destroying the complex network of ecosystems, diminishing the diversity of production, and affecting regional economies, now and in the future.” (*Laudato Si*, para. #134). The Pope suggests that GMO is a technology separated from ethics and he concludes “A technology severed from ethics will not easily be able to limit its own power” (para. #136).

On Agriculture in General

More broadly, the words and direction of the encyclical’s text can be taken as a sharp critique of large-scale, energy-intensive

and chemical-intensive industrial agriculture (factory farming) and the economic system which is its foundation, whether involving transgenic or not, both because of its biological/ecological effects and its social effects on people. The Pope's critique is entirely based on ethics and morality.

Speaking positively, Pope Francis endorses small-scale food production systems "which feed the greater part of the world's peoples, using a modest amount of land and using less waste, be it in small agricultural parcels, in orchards and gardens..." (para. #129). The Pope's emphasis on the Catholic principles of subsidiarity (i.e., maintaining decision-making as close as possible to the people to be affected by the decisions), and the preferential option for the poor, inherently supports smaller-scale decentralized systems which serve those principles over large-scale, concentrated, centralized systems, upon which industrial agriculture depends, which inherently violate those principles.

Further, in para. #164, he endorses the planning of a sustainable and diversified (i.e., polycultural rather than monocultural) agriculture. (Indeed, monoculture has been called the original sin of agriculture, while large-scale food processing is the original sin of food preparation.) Further (in para. #179), he gives the responsibility to local individuals and groups. While noting "... the existing world order proves powerless to assume its responsibilities," he notes that "local individuals and groups can make a real difference. They are able to instill a greater sense of responsibility, a strong sense of community, a readiness to protect others, a spirit of creativity and a deep love for the land" – all of which are necessary components of small-scale decentralized agriculture and which are quite foreign ideas to industrial agriculture.

In para. #180 he speaks of "... planning a diversified agriculture and the rotation of crops ... and the development of techniques of sustainable agriculture." He concludes that paragraph with "New forms of cooperation and community organization can be encouraged in order to defend the interests of small producers and preserve local ecosystems from destruction."

On Other Encyclical Contents Impacting Food and Agriculture

Overall, Pope Francis' encyclical is very concerned about a number of subjects which have major ramifications on the way we practice agriculture and the way we produce food. These include concerns over climate change, biodiversity, the role of technology in our lives, and the role of consumption and the markets in the making of profit and the accumulation of capital. All of these have scientific, economic, and political ramifications. But Pope Francis' concept of "integral ecology" ties all of these issues into global poverty and hunger, into issues of moral and spiritual values and moral choice, and into the expected central concern of a religious leader and a religious institution.

Climate Change: Climate change is as much about how we use and abuse land and how we practice agriculture on land as it is about carbon emissions from the burning of fossil fuel. The pope clearly considers land use, including the destruction of forests for agriculture and monocultural crop production, as causative when it comes to ecological and climate impact and, as well, in its impact in impoverishing people by driving them off the rural land and into urban poverty in the cities. These are direct and indirect results of our industrial way of agriculture which also lead to a loss of natural sequestration of carbon by soil and plants and thus to higher levels of carbon in the atmosphere and the climate change ramifications thereof. (*Laudato Si*, see especially Chap. 1).

Biodiversity: The encyclical clearly recognizes protection of the planet's biodiversity of plants and animals to be both ecologically and spiritually necessary. Such biodiversity is a key to the maintenance of a degree of awe and wonder toward nature, toward the creation, which is necessary for the sustainability of human life on earth. And such biodiversity is threatened and destroyed by the practice of industrial agriculture and factory farming which has its foundation in crop and livestock monoculture, the antithesis of biodiversity. Polyculture, as practiced in traditional agriculture over millennia, with all elements of the farm ecosystem

interacting with and supporting all other elements of the on-farm system, gives us ecological sustainability, upon which economic and all human sustainability must be based. The industrial monocultural system insures a lack of long-term sustainability through destruction of the ecological system (“integral ecology”) and the economic system which rests upon it. (*Laudato Si*, see especially Chap. 1).

Role of Technology: Our attitude toward technology is crucial. Technology is both good and bad – it depends on whether we exercise control or not. We know that technology can help us live a better life. But we also know, as Pope Francis demonstrates, that technology can get out of control and dominate our lives. Humans have long been aware of the danger of technology out of control. The pope reminds us that technology can become an addiction and, as well, a false god to be worshipped. When human technology threatens the ecosystem, we get into trouble. There are many technologies associated with large-scale industrial agriculture/monoculture which are threatening to the ecosystem and, more immediately, threatening to the welfare of human populations who become unemployed, made redundant, and flee to the cities out of necessity. There, many face a bleak and hopeless existence, if not death. Ecology teaches us that we must work with nature, not against nature. Technology too often tempts us to work against nature, thus insuring negative consequences for ourselves and for our planetary home. (*Laudato Si*, see especially Chap. 3).

Consumption and Markets: Pope Francis writes extensively on the worship of consumption and the worship of markets as guiding forces in our lives. The two have become false gods, or at least false prophets. Attitudes toward consumption and markets are directly related to agriculture and food and become very obvious in the enormous waste of resources associated with food production and consumption. Fully 40 % of all food grown or raised in the USA is wasted at some stage of the process from field to plate. And very little of this valuable “waste” is fed to animals or composted into soil amendments – it goes mostly to landfills. Likewise, the market demand for both

cheap and highly processed food causes great demand on energy resources (mainly fossil fuel) and, as well, causes significant emission of greenhouse gases into the atmosphere, while at the same time reducing the natural ability of plants and soil to sequester and hold carbon, creating the imbalance we see with climate change. (*Laudato Si*, see especially Chap. 4).

The papal encyclical *Laudato Si: On Care for Our Common Home* is rife with direct and indirect linkages to the ethics and values of food and agriculture.

On Implications of the Encyclical

The pope is not viewed as a scientist (although Pope Francis does have a scientific background), nor as a leader in business or economics, nor as a politician per se (although the pope does command a city-state independent of all nations, is recognized as a head of state, and likewise commands a corps of diplomats – known as papal nuncios – worldwide). Thus, the pope is not expected to represent nor to speak on these areas of expertise and power. But being a leader of one of the world's principal religions – Roman Catholicism – and, as well, being a major voice for Christianity more broadly, the pope is expected to speak upon, and commands authority to speak on, moral issues, on issues of moral choice. This includes the key moral and justice question of intergenerational equity, namely, what we leave for future generations. The pope is viewed as having expertise in these subjects and thus commands respect in this field of ethics. And since all issues, including those of science, economics, business, and politics, have moral consequence, have moral repercussions, the pope commands authority and respect on the moral aspects of many subjects, not the least this encyclical's questions of environment, natural resources, energy, agriculture, and the science that serves as their underpinning, their foundation. And, indeed, we are told that eating is a moral act since all eating depends upon moral choice. Thus, the pope, although not an agriculturalist, not a farmer, not an agricultural economist, nor an

agricultural scientist, does have credence in matters of agriculture, i.e., the production of food, plant and animal, as well as the system of its processing, preparation, and distribution (i.e., the “food system”), including the health and nutritional effects of the food we eat and the food which is available to us. That authority relates to the moral implications of food production and of the broader food system, for food, its manner of production and distribution, is a moral issue, an issue of moral consequence. Pope Francis thus speaks to the question of agriculture and agricultural ethics with inherent authority, following the particular guideline of Christian teaching. The manner in which food is produced, monoculture versus polyculture; the application of chemicals versus biological methods; the treatment of animals; the use of GMOs; the use of human labor versus machines; the role of technology; the price, distribution, and availability of food, even the nutritional value of food; and, indeed, the treatment of the soil, the water, and the broader natural biodiversity of the ecosystem, are all issues of moral and ethical consequence. The papal encyclical, *Laudato Si: On Care for Our Common Home*, addresses all of those ethical and moral issues.

Conclusion

There is much to be found elsewhere in the encyclical which, while not explicit to agriculture, paints a very clear picture of Pope Francis’ negative critique of large-scale energy and technology-intensive agriculture, his focus on integral ecology, and his positive embrace of small-scale local agriculture, with much confidence that the world can feed itself from the latter.

Population Growth

Thomas Dietz, Jessica Bell and Christina Leshko
Sociology, Environmental Science and Policy,
and Animal Studies, Michigan State University,
East Lansing, MI, USA

Introduction

Debates about population, environmental quality, and resource adequacy stretch back to classical writers but are usually identified with Thomas Malthus’s *Essay(s) on Population* (Dietz and Rosa 1994; Malthus 1803/1992). The basic argument is that human population will grow at a pace faster than increases in the production of food or other resources. This leads to poverty, disease, malnutrition, and other social and environmental ills. Concern with population pressure on natural resources also underpinned Garrett Hardin’s much cited but problematic analysis of the tragedy of the commons (Dietz et al. 2003; Hardin 1968). Hardin argued that common pool resources, such as fisheries or pastures, cannot be managed by communities because continuous population growth will increase demand for resources and encourage self-interested rather than altruistic behavior. The commons collapses. The argument that population growth will lead to problems has been applied to many resources, but it is food, and thus

agriculture, that has been at the center of most debates about Malthusianism.

The logic of the Malthusian argument – ever increasing human population will lead to food shortages – may seem compelling. Populations of living organisms can increase exponentially, doubling at a pace that is roughly equal to 70 divided by the percentage growth rate. (Formally, the doubling time is $\ln(2)/(\ln(1 + r))$ where r is the growth rate.) Thus, a population growing at 2% per year doubles about every 35 years and one growing at 4% per year doubles about every 17.5 years. Nonlinear systems such as exponential growth are difficult for humans to understand, so the speed at which populations can grow is often startling. Growth of the total human population over the last century has been unprecedented in human history. In 1900, world population was estimated at 1.7 billion. By 1950, it had grown to 2.5 billion, an increase of less than 1 billion in 50 years. By 1975, it had increased to 4 billion, an increase of 1.5 billion in 25 years. By 2000, there had been an increase of 3 billion for a world population of 6 billion. As of this writing (November 2013), world population is estimated at 7.1 billion and is projected to reach 9.4 billion by mid-century (U.S. Census Bureau 2013). This rapid growth, and its exponential character, underpins concerns about the likelihood of increasing production of food and other resources at a comparable pace.

Malthus's argument was primarily about the pace of population growth, not about population size. In particular, he argued that if population growth is rapid, it will exceed the rate of increase in food production. In contrast, some have expressed concern about the size of the human population, arguing that we have, or will, exceed the earth's carrying capacity – the population an ecosystem can support over the long term. However, human use of resources and the stress humans place on the environment depend not just on the size of the human population but also on what is consumed and how it is produced, including how waste from production and consumption is disposed. Because both consumption and the technology used for production can change quite rapidly, thoughtful analyses have

questioned the utility of the carrying capacity concept when applied to humans (Cohen 1995). While both the size and the rate of growth of the human population warrant serious ethical consideration, they cannot be considered in isolation from thinking about what is consumed and how what is consumed is produced.

What causes population growth? Putting migration aside, population grows when the number of births exceeds the number of deaths. Improvements in public health, including better nutrition and reduction in infectious disease mortality, have substantially lowered the death rate in most nations in the twentieth century. Initially, birth rates remained higher than death rates, leading to rapid population growth. In many countries of the world, lower infant mortality rates; the education, employment, and empowerment of women; better access to contraception and abortion; and improved old age security eventually led to reduced birth rates. In time, and after substantial population growth, death rates and birth rates came into coarse alignment and population growth rates slowed to roughly zero. The overall process is called the demographic transition. It occurred in Western Europe in the nineteenth century and in Asia and Latin America in the last half of the twentieth century but has not yet played out in Africa or the Middle East.

After World War II, the start of the demographic transition – declining death rates – led to rapid population growth in what are typically labeled the developing nations. Concerns about Malthusian outcomes from this growth were motivated in part by a perceived link between rapid population growth, poverty, and the potential for political instability and Communist revolution (Hoff 2012). Influential analyses of economic development suggested that while population growth would not prevent increases in affluence, slower population growth would facilitate economic development. The result was substantial efforts to promote family planning and lower fertility in the developing world. By the 1960s, concerns with whether or not food production could keep pace with the demands of a growing population were at center stage in discussions of population. In the mid- to late 1960s, stress on the

environment from both consumption and population growth also became a major part of public debate about population growth. At about the same time, US conservative support for family planning and population limitation shifted to opposition as free market ideology and alliances with antiabortion religious groups became part of the conservative agenda.

The dynamics that link population size to food production, consumption, and environmental impact are complex. First, throughout history, most human populations have taken steps to limit fertility through a variety of mechanisms, including contraception, abortion, extended nursing, infanticide, abstinence, and delay in age at marriage. Unrestricted population growth of the sort anticipated by Malthus seems more the exception than the rule. So the scale of human population, and thus food demand, is subject to human agency, although there are substantial time lags between changes in fertility and shifts in the dynamics of population size. Second, consumption matters. Much of the demand for food in the contemporary world comes from people seeking food stuffs that are harder to produce and have greater environmental consequences than would be required for a nutritionally adequate subsistence diet. Patterns of consumption have varied tremendously over time, across societies and across social groups within a society. But in recent decades, there is a general tendency for increasing per capita affluence to shift demand towards foods, especially animal products, that are harder on the environment than the diets of the less affluent (Steinfeld et al. 2006). Thus, food demand and the impacts of food production are driven by the composition of consumption as much or more than by the sheer number of people. Finally, the techniques used to produce food also vary tremendously over time and across societies. Malthus assumed that increases in food production could only advance linearly. But changes in agriculture, including changes in the social and economic organization of food production, have led to increases in global and regional food production at a pace much more rapid than Malthus had anticipated – the “Green Revolution.” Increases in production since about 1950 have

generally outstripped increases in the size of the human population, so on average, per capita food production has increased since the middle of the twentieth century (Food and Agricultural Organization 2013). Of course, some of these changes in agricultural technique have had problematic environmental and social consequences.

Even with an increase in global per capita production, there have been tragic incidences of starvation and famine, and a substantial fraction of the world’s population continues to be malnourished. But most analysts acknowledge that malnutrition and starvation are more of a function of how food supplies are distributed than to any absolute lack of food at the global or even regional scale (Ravallion 1997). Whatever ethical problems arise around malnutrition and even starvation, the causes are not primarily increases in overall human population size, but rather problems of food access among the poor, the displaced and the disadvantaged. Tragically, violent conflicts and natural disasters can create a “population explosion” of refugees in areas that are not well suited to provide sustenance for them. But the underlying cause of these tragedies is not population size per se, but rather inadequate arrangements to cope with such situations.

Analyses of population and food now acknowledge that links between population and food cannot be considered in isolation from climate, water, energy, biodiversity, and many other factors. Current thinking considers food and agriculture as part of a set of complex interactions between humans and the biosphere, often called coupled human and natural systems (Rosa and Dietz 2010). Food production is only one stress humans are placing on the environment, and how ecosystems and the biosphere respond to multiple stresses is undoubtedly more complex than simply the sum of the individual stresses. For example, increased demand for grains might be met by more intensive cropping. But that in turn will require more fertilizer, pesticides, and water, and each of those inputs places stress on the environment. In parallel, environmental change, including climate change, may make it difficult to provide those inputs. In many regions of the world, climate change induced by human use of

fossil fuels, in part to support food production, is changing hydrological regimes so that in the future the water needed to increase food production may not be available. The discourse has moved from a Malthusian concern with population and food supply to a concern with population, consumption, and technological choice as interacting stressors. The conceptual shift has been from a concern raised by Malthus – whether food production could keep up with human population growth – to an acknowledgment that for the first time in planetary history, humans dominate earth systems process. The resulting changes are dramatic and problematic and perhaps even catastrophic. Population alone is not the cause of these impacts; rather, they are driven by the joint effects of population, consumption, and technology.

Of course, slower population growth makes it easier to enhance human well-being, including the provision of an adequate food supply, and easier to protect the environment. So this entry begins with a discussion of the interplay between population, consumption, and technology. This sets a context for the discussion of the ethical issues that arise around efforts to slow the rate of growth and/or the size of the human population. The final section examines efforts to define an optimal population size.

Balancing Human Population with Resources and the Environment

Slowing the pace of human population growth is only one strategy to provide adequate food to the world's population. Other complementary approaches include increasing food production, shifting consumption patterns, and reducing waste. Thus, the ethics of population, food, and agriculture inevitably entrains broader discussions.

Increasing Food Production. The Green Revolution substantially increased food production in the later twentieth century, and the dire shortfall in food availability in many mid-century projections was avoided. However, the environmental and social stresses that accompanied the

Green Revolution raise questions about whether or not a continuation of this strategy is an acceptable option for the future, even if it is technologically feasible. Agriculture and other human activities have come to have a major influence on many biogeochemical cycles and are otherwise transforming the planet (Rosa and Dietz 2010). Thus, increasing food production as a strategy for keeping food supply in balance with human population engages ethical issues that are discussed in much of the rest of this volume.

Shifting Consumption and Reducing Waste. Shifting consumption and reducing food waste can complement increased production as a means of meeting the needs of a growing population. For example, approximately one-third of the global cereal production is fed to animals, converting large amounts of grain to modest amounts of animal protein (Erb et al. 2012). With growing affluence, the proportion of the diet in meat products tends to increase sharply. So one response to food shortages could be for the affluent to move away from diets heavy in animal products to those more reliant on plants, along with a continued emphasis on plant-based foods for those already consuming modest amounts of animal based foods. This response to the food needs of growing human populations thus entrains the ethics of consumption and, in particular, of vegetarianism and veganism into the discussion of the ethics of population growth (Fox 2013). In addition to dietary shifts, the current system involves considerable food waste. Best estimates indicated that between 30% and 40% of food in developed and developing countries is lost to waste (Godfray et al. 2010). Reducing such waste could help increase the amount of food available for consumption without the need for increased production.

Emerging technologies could yield more food with less environmental stress. Sustainable intensification, such as the integrated management of waste in livestock production or no-till cropping and precision agriculture, may provide methods of production that place less stress on the environment than traditional practices (Godfray et al. 2010). Biotechnology, including genetic

modification, could increase yield and nutritional value of what is produced while reducing environmental impacts. Promising as such approaches may seem, many scholars question the ethics of many aspects of biotechnology and wonder whether technological change driven by market motivations will be beneficial overall.

In general, increases in food supply do not necessarily translate into more food for the malnourished when resources are allocated according to a market logic emphasizing profits, as described by neoclassical welfare economics. Some argue that there is a right to the food needed for an adequate diet, which troubles a utilitarian approach. As Mares and Pena put it, food is not a commodity, but is instead, “a relationship that forces us to stretch our understanding of what it means to grow and eat food justly” (Mares and Pena 2011, p. 199). A virtue ethics stance would implicate high levels of consumption and waste whether or not they were profitable and also interrogate food systems that encourage inequity among producers, harm to the environment, and adverse effects on the well-being of domesticated animals (Thompson 2010). Most work on virtue ethics has focused on the local to national level, so analysis of how it may provide insights into the global food system is much needed.

Clearly, concerns with population, environment, and agriculture are intertwined with issues of consumption and production in ways that touch on nearly every other entry in this encyclopedia. However, there are two topics that are nearly unique to population ethics: concerns with the control of human fertility and concerns with optimal population size.

Concerns with Fertility Control: Cultural Norms and Individual Rights

Many cultural traditions, and especially religious traditions, include norms about gender roles, contraception, ideal family size, child gender preferences, and abortion. They thus offer an ethical framework for thinking about human fertility control. Of course, official policy of a religious

institution may not be followed by all laypeople in that faith (e.g., for generations, many Catholics have used birth control methods proscribed by the Vatican). And official doctrine may be more progressive than public images and common practices would indicate (e.g., a fatwa issued by Iranian clerics after the Revolution approved the use of family planning as long as the husband consented). However, religious norms have a strong influence on ethical decisions for many individuals and governments and sometimes may trump concerns regarding the effects of increased human population on the environment. In other cases, where religious norms raise concerns with the welfare of the poor or with environmental protection, they may encourage concern with population size and growth.

Of particular importance are religious teachings and cultural practices about gender and fertility behavior. One of the best established findings of decades of research on human fertility is that increased education, equality, and empowerment for women, coupled with access to family planning services, including abortion, lead to reduced fertility (World Bank 2012). But moves to promote gender inequality and access to contraception may contradict religious teachings and cultural norms that call for women to adhere to traditional roles, including a major emphasis on childbearing and proscriptions on some means of fertility control.

A parallel ethical conflict can arise with libertarian views that reject the legitimacy of a collective influence on individual decision making. Such a position would suggest that the collectivity, whether in the form of the state or the community, has no justification for suggesting how many children an individual or couple may have. In contrast, some have argued that strong policies and even coercive measures are justified in slowing the rate of population growth and limiting human population size (Derrighi 2001). While many governments in the developing world have instituted policies intended to slow population growth, the most notable is China's one-child policy, which sanctioned urban couples who had more than one birth, a policy China reversed in 2013.

Concerns with the Optimal Size of the Population

Classic utilitarianism argues for maximizing total population welfare defined as the sum of the welfare of each individual in the population. Derek Parfit noted the “Repugnant Conclusion” that can follow from this logic (Parfit 1984; Arrhenius et al. 2014). A very large population in which everyone has minimal quality of life may provide a larger “sum of welfare” than a smaller population with higher average quality of life but smaller aggregate quality of life. Under the “sum of utilities” logic, substantial population growth may be warranted, as long as every member of the population could be provided with sufficient resources so that the aggregate well-being remains greater than it would for a smaller but better off population. The original argument about the repugnant conclusion considered only human populations, but the logic could be expanded to utilitarian formulations that take seriously the well-being of nonhuman species (Frey 2011).

The repugnant conclusion is predicated upon the concept of welfare as a single additive scale. However, there are alternative ways of aggregating welfare into a measure of value. For example, maximizing the average, rather than the sum, of well-being could favor small populations with very high welfare. Another strategy is to introduce a variable value principle, so that the value of adding worthwhile lives to a population varies with the number of already existing lives in such a way that additional population has more value when the number of these lives is small than when it is large. This is an elaboration of Bernoulli’s argument that well-being increases proportionally to the logarithm, not the raw value, of income. Another way around the problem is to introduce a minimal well-being standard, so that a person’s life only contributes positively to an outcome if the quality of the person’s life is above the standard, although what constitutes an appropriate critical level is subject to debate. Still other ethical theorists argue that we should focus on frustrated and satisfied preferences, with a frustrated preference counting negatively whereas satisfied preferences having a neutral value. This could be

extended to Nussbaum’s capability argument – larger populations are not to be preferred to smaller populations unless that increased size enhances the ability of all to realize their capabilities (Nussbaum 2006). Finally, some philosophers assert that Parfit’s conclusion is not so repugnant after all. For example, it is argued that while a life barely worth living stands in stark contrast to a privileged life, a life barely worth living is not ipso facto unethical.

Summary

The ethics of population, food, and agriculture inevitably engages a wide variety of other ethical issues related to the environment, social justice in the allocation of resources, the role of cultural and religious institutions in society and individual choice. The question of optimum population size leads to deep inquiries into the problem of aggregating across individuals in ascertaining the collective good. Thus while an important topic in itself, population ethics is also an inherently complex and interdisciplinary area of inquiry.

Introduction

The following general description of the pork supply chain is from the perspective of a farmer beginning with no farming operation to decisions concerning scale, housing, feed, processing, and so on, ending with an economically viable operation and pork products available for the consumer. Within each of these decision points, the authors have included key value domains where there are choices or trade-offs in tension between economic viability, social equity, environmental or ecological integrity, or animal health and welfare.

What follows appears as a linear description of the decision tree for someone interested in getting into the pork supply chain; however, many of these choices are not linear in nature but rather are nested or interconnected in how one must weigh the trade-offs involved with the overall farm plan. Complicating the ethical issues embedded in the supply chain is the dynamic nature of the various decision points and the associated risk, such as volatility of feed costs or global market pressures.

Choice of Production Approach or System

A farmer who is considering pork production for his or her farm enterprise will consider the type of pork production system that best fits with their skills, resources, philosophy regarding animal agriculture, and desired economic outcome. It is likely that the first choice our farmer must face is whether he or she would like to be an owner or to be a contract grower. Ownership of a pork production reflects various levels of investment in land and buildings, labor, mechanical skills, and marketing skills. Pigs may be raised very intensively (controlled environments and proven technologies) or very extensively (outdoors, using crop fields post-harvest, pastures, and buildings in various combinations) or with some mix of these approaches. Owned enterprises may be of various scales, but in general intensively managed farms are the largest.

The benefits of intensive, highly coordinated production have been discussed for decades. Hurt and Zering (1993) were one of the first to study industrialization in pork production and discuss

the reasons for the growing adaptation of the intensive approach. For owners of swine farms, technology improvements in genetics, nutrition, disease control, and facilities led to increased production efficiencies and significant return on investment. Significant gains from scale economies were also realized by the implementation of a highly coordinated production-processing system. Hurt and Zering's suggestion at that time has been realized; that there would be further movement toward large production units which are more highly coordinated with the packer and the domestic and foreign consumer. Indeed, consumers have been the beneficiaries of the intensive pork businesses which produce and market at lower costs and with acceptable quality, extreme safety, and consistency.

There are significant economic advantages with increasing size and specialization in pork production. Advantage may come from economies of scale (MacDonald and Ollinger 2000; Marchant 2007) or scale efficiency (increasing returns with the same production technology as operation size increases; Key and McBride 2007). When a farmer elects to operate within or outside of the intensive commodity supply chain, there are significant consequences associated with the economy of scale. These forces will only continue to grow as the global population continues to grow to the projected nine billion people by 2050 (UN 2004). Compounding these forces of scale is the changing diets of developing nations to mirror that of the developed world with increased meat consumption. This "feed the world" ethical stance is often in tension with a regional food system approach. More extensive pork producers who choose to operate outside of a coordinated or integrated pork chain may make this choice based on an ethical stance of freedom to make on-farm production decisions more closely guided by regional sensitivities to place, community, terroir, animal welfare, or niche markets.

The substantial increases in farm productivity with large, specialized farming systems are associated with the use of production contracts. In 2009, just over 70% of US pork sold was raised using production contracts (McBride and Key

2013). Contract production is a formal agreement whereby the owner–contractor of the pigs pays the contract grower to care for the pigs in the grower’s facilities with inputs furnished by the owner–contractor. Contract growing in the pork industry has an interesting history that traces back to entrepreneurship; relatively lenient environmental regulations; few alternative economic opportunities; familiarity with production contracts in the poultry industry; less expensive land, labor, and capital; and lenders willing to finance new grower facilities.

Contract growing initially took hold in the southeast part of the USA. The decline in US tobacco production in the 1960s and 1970s was a contributing factor (Hurt and Zering 1993). Here contract growing was a welcome relief for many of these farmers who were facing severe financial hardship and lack of knowledge to support the transition to an alternate farm product. Contract production provides farmers with a farm plan, resources, and a contract securing income if they fulfill the agreement to care for the pigs. Production contracts absorb risk in the form of a low-interest loan to the farmer. Contract growing is critiqued for creating greater concentration of power, knowledge, and revenue in the owner–contractor thereby decreasing the diversity or pluralism of farm practices lending to a so-called democratic food system. Alternatively, these contracts provide a co-benefit that forces the farmer to comply with an animal welfare audit (Grandin 2010).

Labor

One concurrent and confounded part of the decision whether the farmer has the capacity or desire to engage totally or in part in an intensive farrow-to-finish system or to participate in some form of specialized, part or all extensive, swine farming enterprise may involve an ability and liking for managing hired labor. This decision about the scale of either intensive or extensive farming is driven largely by how much land is accessible and how much labor can be successfully overseen. When considering labor, one looks at whether this is a farming family with some percentage of farm labor coming directly from the family and

what percentage of labor will come from outside of the family. Labor and treatment of the laborers come with a unique set of ethical issues relating to wages, labor practices, employment of migrant labor, and the management of family income. Intertwined are ethical issues concerning worker safety and health, low pay, immigration status, and impact of significant cultural change in a traditional, rural community (Honeyman 1996). Although a serious prospect 15–20 years ago, it has now been realized to some degree that the changing labor demographic does not have to be as great a concern as initially thought (Hassan 2011).

Feed Procurement

Whether large or small scale, intensive or extensive, organic or conventional, all pork production systems require provision of feed for the nourishment of their swine. Pigs are monogastric omnivores and require energy, essential amino acids, vitamins, and minerals in their diet. It takes approximately 1000 lb of feed to raise a pig to market weight. Traditionally, corn and soybeans have been the primary feedstock used in blending a nutritionally balanced diet for pigs in intensive production systems in the USA. Assuming a whole herd carcass feed efficiency of 4.0, an average carcass weight of 200 lb, soybean meal yield per bushel crushed is 79.2%, and all feed (all diets from all production phases combined proportionally) is comprised of 78% corn and 17.5% soybean meal, then about 21.7% of the corn and 20.3% of the soybeans grown in the USA in 2012 (NASS 2013a, b) were utilized for pork production. Alternative feedstuffs and the grazing of pastures and fields are more likely used in extensive production.

For a given desired production approach and scale, feed may be procured via crop production within the system. Another series of decisions must be made concerning crop production for the farm if the farmer will be growing their own feed. If the farmer is growing under a contract agreement, the feed is grown or purchased; it is manufactured off-farm by the owner–contractor. Embedded in decisions about crop production inputs are decisions regarding fertilizer application,

tillage, weed control/management, insect control/management, implement use, transportation, storage, and environmental impacts. There are ethical stances associated with these practices. For example, there is an inconclusive body of research pointing to the persistent use of glyphosate and declining soil microbial health. Farm implements are powered by fossil fuels which contribute to global atmospheric CO₂. Hundreds of studies have been conducted to assess the impact of atrazine on wildlife and human health. Runoff from the use of agricultural synthetic nitrogen has been linked to several “dead” or hypoxic zones in coastal waters.

The substantial use of farmland for animal feed is an area where one often sees multiple value stances in tension. The use of federal funds to subsidize corn and soy production for animal feed has been questioned. In 2014, price support programs were eliminated from the Farm Bill. Federal subsidies of corn to support ethanol production further complicates how one might weigh the trade-offs associated with feed for pork production. In 2013 farmers saw corn prices reach an all-time high with some responsibility believed to be a result of the ethanol subsidy. This increased input cost drove up the cost of pork production for farmers, posing the question whether corn should be used for animal feed or a “renewable” energy source.

Over 90% of corn in the USA is genetically modified (GM) and over 93% of the soy is GM. Genetic modification of these two crops raises many ethical issues to consider. Central to this debate is whether life should be patented and controlled by private industry. There is concern regarding the long-term effects of GM crops on nontargeted species, soil microbial populations, and gene flow in the ecosystem (UNFAO 2001). The science behind the safety of long-term consumption of GM food and human health is inconclusive (Rich 2004).

The use of alfalfa hay as a feedstuff for gestating sows in outdoor or alternative pork production should not be overlooked. In 2010 the US Supreme Court lifted a ban prohibiting the planting of alfalfa seed and allowing Monsanto Corporation to sell the seed to farmers. This decision and

practice of growing GM alfalfa puts organic growers at risk of genetic contamination. Currently only 1% of the alfalfa grown in the USA is certified organic.

Feed additives such as antimicrobials (commonly referred to as antibiotics), clay binders, enzymes, and flavorings may also be decision points for the farmer. Of these ingredients, the addition of antimicrobials to feed is the most contentious. The use of antimicrobials in animal feed has been linked to so-called superbugs or antibiotic-resistant strains of human germs (Fitzgerald 2012).

Housing

Before the 1960s, most pork in the USA was raised in outside lots or on pasture systems. With the development of slotted floors, automated feed systems, ventilation, gestation and farrowing stalls, and liquid manure handling equipment, it became possible for producers to more easily care for larger numbers of animals and to do so provide protection from variations in environmental factors including temperature, precipitation, sun, parasites, and predators. Enclosed buildings also made it practical to farrow year-round, rather than seasonally. This was the beginning of intensive production systems also known as concentrated animal feeding operations or CAFOs used for over 75% of pork production in the USA and by a rapidly increasing number of producers globally. This system of production also allowed farmers to minimize labor per unit of product, obtain year-round production for maximum use of facilities, and allow for increased profitability of the farm enterprise (McBride and Key 2013). This decision point for the farmer is tightly bound to instability in feed prices. In recent years, it has become increasingly difficult to afford keeping pigs outdoors due to the high price of corn and other feedstuffs, possibly a contribution of expanded efforts to use increasing amounts of biofuels.

Most swine today are raised in “all-in, all-out” (AIAO) systems, where each room or building is completely emptied and sanitized between groups of pigs. Each new group of pigs enters a freshly disinfected environment and stays there for this

phase of their life. The facility has a separate room or building for each group of pigs weaned, with extra space if needed to allow workers time to clean the room before the next group of pigs. AIAO animals in each room are of a uniform age and size and are isolated to the extent possible to decrease the possibility of diseases spreading from older animal groups to younger ones. The primary advantages are that disease spread can be better contained; animals are less stressed because they remain with the same age and social group throughout their development; and complete cleaning and disinfecting between groups is possible. In the last few years, some producers have constructed “wean-to-finish” barns where pigs go immediately after weaning and stay until market. This combines the nursery and grow-finish phases of production. These barns provide substantially more space per pig than is needed initially, but provide the advantage of only moving pigs once during their lifetime. This reduces stress on the animals and saves labor since buildings are not cleaned until the hogs are marketed.

Twenty to thirty years ago, this approach of housing swine 100% of the time was called “confinement”; today is called “controlled environment.” Keeping swine in barns all of the time has significant ethical issues related to the welfare of the animals. Included is the housing of swine in stalls and densely populated pens. There are competing value domains and differing forms of expert knowledge and assessment utilized to measure the welfare of pigs in confinement. A common concern in this type of housing is the denial of species-specific behaviors, freedom of movement or animal agency, group housing (pigs are highly social), or enrichment (cognitive enrichment with pigs reduces stress and aggression). Pigs in extensive systems, with access to fields and/or pasture, may spend more, depending on the season, than 50% of their life rooting/seeking. The denial of this species-specific behavior in intensive systems is considered a cause of stress, boredom, and stereotypic behavior in pigs. Farmers must weigh the trade-offs between perspectives concerning the welfare of the animal and economic viability of the farm enterprise.

Protecting the Environment

Large-scale, intensive animal production, including pork, is viewed as a serious environmental concern. Disagreement in value domains and expert knowledge exists between producers, government, advocacy groups, and consumers. In tension is the economic viability of the farm enterprise with the risk for negative environmental impacts. USEPA’s 2004 *National Water Quality Inventory* indicates that agricultural operations, including animal feeding operations (AFOs), are a significant source of water pollution in the USA. States estimate that agriculture contributes in part to the impairment of at least 94,182 river miles, 1,670,513 lake acres, and 792 estuary square miles. Agriculture was reported to be the most common pollutant of rivers and streams. Potential sources of manure pollution include open feedlots, pastures, treatment lagoons, manure stockpiles or storage, and inadequately managed application to fields. Ammonia, nitrogen, phosphorus, pathogens, and odorous compounds are the pollutants most commonly associated with manure. Manure is also a potential source of salts and trace metals and, to a lesser extent, antibiotics, pesticides, and hormones.

These pollutants can impact surface water, groundwater, air, and soil. In surface water, manure’s oxygen demand and ammonia content can result in fish kills and reduced biodiversity. Solids can increase turbidity and smother benthic organisms. Nitrogen and phosphorus can contribute to eutrophication and associated algae blooms which can produce negative aesthetic impacts and increase drinking water treatment costs. Turbidity from the blooms can reduce penetration of sunlight in the water column and thereby limit growth of sea grass beds and other submerged aquatic vegetation, which serve as critical habitat for fish and other aquatic organisms. Decay of the algae can lead to depressed oxygen levels, which can result in fish kills and reduced biodiversity. Eutrophication is also a factor in blooms of toxic algae and other toxic estuarine microorganisms.

These organisms can impact human health as well as animal health. Human and animal health can also be impacted by pathogens and nitrogen in animal manure. Nitrogen is easily transformed

into the nitrate form and, if transported to drinking water sources, can result in potentially fatal health risks to infants. Trace elements in manure may also present human and ecological risks. Salts can contribute to salinization and disruption of the ecosystem. Antibiotics, pesticides, and hormones may have low-level, long-term ecosystem effects.

One must also consider the detrimental impacts to environmental and public health through the airborne emissions sourced in pork production. Significant research has been done on the air quality surrounding pork operations, yielding varied negative effects in adjacent communities. Researchers have described serious respiratory reactions such as chronic obstructive pulmonary disease (COPD) in some swine farm laborers working in enclosed swine housing, with positive health effects in those who wear respirators (Monso et al. 2004; Dosman et al. 2000). This is due primarily to the chemicals found in the air, manure, and dust (Cole et al. 2000). Hydrogen sulfide, carbon monoxide, and methane are the significant gases of concern to the safety of pigs and people. Methane is a product of anaerobic digestion in the depths of the stored manure and is released into the air above the manure. It provides a risk of barn fire or explosion. The health of the workers and community also brings to light the issue of environmental justice, as typically the facilities are located in low-income areas and employ low-income individuals, who often happen to be minorities. This environmental injustice often adds to the existing social imbalance and the stigma attached to these communities (Wilson et al. 2002).

The use of hormones to regulate the estrus cycle of sows and gilts allows for more efficient use of gestation and farrowing facilities, thereby improving the overall economic viability of the farm enterprise. However, increasingly the use of hormones in animal agriculture is being challenged. Estrogens, progestogens, prostaglandins, and other hormones and/or their metabolites, from human and animal use, disposed of into surface and groundwaters have been implicated in the reduction in sperm counts among Western men

(Luconi et al. 2002) and reproductive disorders in a variety of wildlife (Safe 1995).

Also of note is the water usage involved in the production of pork along the entire chain. An estimated 41.3 billion gallons of water is used annually in the USA alone for swine production, most of which (62.2%) goes toward swine finishing. The remaining nearly 38% is used in farrowing (33.4%) and nursing (4.4%) the swine, with 80% of the total usage being animal drinking water. This consumption not only adds to the growing crisis of water shortages but, from the perspective of the farmer, can also increase costs drastically. Reducing water usage by only 5% can save upwards of 35,000 gal of water (assuming a 1000-head operation) and \$420 annually, with both numbers growing as water conservation increases (Pork Checkoff 2011).

Market Access

Pork is the most widely consumed meat in the world, 43% of world meat consumption by species (pork, beef, poultry, other). When deciding on the system and scale of the farm enterprise, potential farmers must consider the market conditions in their region and what type of market (direct to packer, spot-collection point, custom butcher, direct to restaurant, farmer's market, CSA, or other arrangement) is currently available, could be developed, and is most desirable to work with. Market access is pivotal for success. The need for consistent, reliable sources of a particular quality is seen at all scales. What and who defines "quality" is certainly an ethical issue to be considered. Embedded in pork quality are variances in fat, flavor, market weight or size, curing, fresh, frozen, or use of growth-securing antimicrobials.

In intensive production, nearly all of procurement by packers and process is direct, with marketing agreements (Grimes and Plain 2007). In 2007, 60% of independently produced hogs were sold through some form of market formula or purchase arrangement; 33.4% of hogs marketed were packer-owned or packer-sold. Procurement managers are willing to pay a price premium to secure the quality and number of hogs they need. The fact that less than 10% of hogs are sold in spot

or markets involving bids has led some to question whether enough hogs are sold on the spot market to sufficiently represent actual supply and demand conditions and derive an accurate price for hogs.

Here too one must consider time as a constraint or a value stance. Does the farmer value the efficiency and speed of production or rather a slow food ethic (Paxson 2005) where speed and efficiency are replaced with slower-growing breeds, longer time to market, and slower pace of farm family life? It can be demonstrated that reliance and reduction of off-farm inputs is favored by small- to mid-scale independent farm systems. Small- to midsize-scale pork production is often correlated with USDA-certified organic, pasture-raised, multispecies-integrated, or animal welfare-certified farms. These practices can represent a value stance of the farmer or can be an economic strategy to capture a portion of the growing niche market for this type of pork. This demonstrates how one value domain, economic viability, can drive other value domains such as animal welfare or ecological integrity. Coupled with this driving force is again the need to produce to scale with consistent quality.

Transport

Market weight or finished hogs are then transported to slaughter. The 28-h law was first enacted in 1873 and applied exclusively to rail transportation of cattle, sheep, swine, and other animals, requiring that animals not be confined for more than 28 consecutive hours without being unloaded for feed, water, and rest. This law was amended in 1994 and further clarified by the USDA in 2006 that livestock transported by truck are subject to regulation requiring that they be off-loaded for feed, water, and rest after 28 consecutive hours in transport. This decision of transport is tightly wedded to the location and availability of USDA-inspected slaughterhouses. For the small- to mid-size farmer, the lack of processing facilities within a 2-h drive severely limits their ability to choose especially if seeking to grow certified organic or certified humane pork. There is a small but growing movement to provide mobile abattoirs for processing.

Harvest

Once the animals have arrived at the processing facility, they are unloaded into the lairage (holding pens) where preslaughter welfare conditions should be optimized. The ideal condition for both meat quality and welfare of the animal is short transport time and a sufficient lairage rest. Good lairage conditions give pigs a time to rest and rehydrate. The amount of lairage time may vary from 0.5 h to 24 h, as it is dependent on climate, time in transit, quality of transport, and conditions in the lairage (e.g., separate pens to avoid comingling of animals from different farms). After resting, the animals are then brought to the slaughter line or kill floor. The Humane Slaughter Act of 1958 is a federal law designed to reduce pain and suffering of animals during slaughter. The law is enforced by the USDA Food Safety and Inspection Service. Compliance to this federal regulation is often an area of concern and has paved the way for the adoption of Temple Grandin's humane slaughter auditing process. Grandin's work over the past two decades has dramatically changed slaughterhouse conditions, process, management, and self-regulation with the development of her welfare audit protocol (Grandin 2003). The audit is an objective scoring at critical control points in the process. This has now become a voluntary industry standard with corporations such as McDonald's, Burger King, and Wendy's requiring the audit of their suppliers.

Processing and Distribution

From the cooler, carcasses may be managed in several different ways. They may be sold for wholesale or restaurant distribution. More often the whole carcasses of niche swine find their way into restaurants and neighborhood-operated butcher shops. Carcass may be split into primals (major portions of the animal) and shipped to other plants for further processing, exported, or shipped to stores for customized cuts. Some restaurants may buy primals. At issue here is identity preservation as well as consistently providing customers the product the seller claims to provide 100% of the time. Identity preservation is important for enhanced food safety, but it has been a

cause for concern when incorporated into enforcement of country of origin labeling. Vertical integration has allowed for the expeditious and affordable distribution of large amounts of meat through large grocery chains. The processing of the meat is the responsibility of the company all the way to the branded productions in the meat case at the store. Finally, it is important to some to remember that the harvest of swine results in more products than just pork. Several valuable products or by-products, in addition to meat, come from swine. These include insulin for the regulation of diabetes, valves for human heart surgery, suede for shoes and clothing, and gelatin for many food and nonfood uses.

Summary

Ethical issues exist throughout the pork supply chain for both producers and consumers. They are very important and must be addressed using deliberative skills, patience, and humility. Knowledge and investigation of the complexity of the trade-offs involved in pork production along with an increased understanding of what is actually taking place during production, harvest, processing, and distribution are essential to the full discussion.

Poverty and Basic Needs

Introduction

Dissatisfaction with purely monetary measures of poverty led to the development of the basic needs approach (BNA) during the 1970s. Its main foundation is a consequentialist ethic that argues that a good society is one in which all people will be able to meet their basic needs. A person is said to be poor if he or she is unable to meet his or her basic needs. In general, the BNA is more concerned with poverty experienced in the present than with long-run growth per se and more concerned with inequality in the distribution of growth's benefits than its absolute speed.

Beyond this basic foundation, however, there is a great deal of debate and disagreement within the movement. As discussed below in greater detail, some practitioners contend that basic needs are confined to a minimal set necessary for the sustenance of human existence, while others focus on ensuring complete well-being and a list of needs that is ever expanding by design. While the BNA is inherently multidimensional, there is disagreement over how to deal with this multidimensionality in quantitative analysis. These internal disagreements shortened BNA's brief prominence in development thinking. It has since been growing in importance, thanks to the Millennium Development Goals (MDGs) and Latin American practitioners.

History

Some of the roots of the basic needs approach can be traced as far back as Aristotle, who identified four groups of needs. The two most relevant groups are "that which must be if life or existence is to be" and "that which must be if some good is to be achieved or evil avoided" (Reader 2006, p. 339). Rowntree measured poverty in early twentieth-century England based on calculating an income level necessary to meet the "human needs of labor" (Glennerster 2004, p. 25). Wiggins (1998) attempts to give the most concrete definitions of having an "absolute" need for a particular object – a need which would cause significant harm if unmet and can only be met by that particular object. Absolute needs are "entrenched" when it is exceptionally difficult to imagine a reality where the person in question did not have an absolute need for that object. Lastly, entrenched, absolute needs are "basic" if it is a reality on par with a natural law that makes it so the person has an entrenched, absolute need for that thing.

Maslow's (1943) famous hierarchy of needs also doubtlessly played a role in the BNA's early development. The original hierarchy identified five levels of needs, ordered from the physiological and safety and security needs which are necessary for existence to the social, esteem, and

self-actualizing needs requisite for human growth and development. Tay and Diener's (2011) test of Maslow's hierarchy finds that while each of the needs Maslow identified is significantly correlated with happiness worldwide, the expected hierarchy is not supported by their data. Türkdoğan and Duru (2012) determine that the five basic needs from psychology's choice theory (survival, love and belonging, power, freedom, and fun) are significant predictors of subjective well-being among university students. Even though survival was the need that was least fulfilled, they suggest that freedom (or self-autonomy) and fun were the most important drivers of variation in subjective well-being.

US President John F. Kennedy's Alliance for Progress was established in 1961 explicitly "to satisfy the basic needs of the [Latin] American people" (Dixon 1987, p. 129). During the same period, the US monetary poverty line was based loosely on the cost of obtaining a minimum, emergency diet (Chambers 1982). In other countries, simple poverty lines were also based on the ability of a household to obtain enough food. However, this was often limited to the ability to obtain the primary staple (e.g., rice, maize, wheat, potatoes, or cassava). Very little attention was paid to nutritional adequacy or intrahousehold food distribution in the earliest measures. This tendency was seen again during the 2006–2008 food price crisis when governments that took action primarily focused on staple crop access rather than on nutrition and dietary diversity.

There was increased focused on basic needs during the 1970s in part because of the world food price crisis of 1973–1974. Soaring food prices led to hunger and brought to the fore the need to address this most basic need, particularly since the same amount of money would not purchase as much food. BNA was often couched within a discussion on the ability of societies to provide their citizens' basic needs within environmental constraints. The development of the BNA was therefore intimately related to the development of environmental consciousness.

Basic needs as a development paradigm were fostered by a series of influential publications supported by major donor organizations. These

included the Cocoyoc Declaration (1975, p. 896) by UNCTAD and UNEP which forcefully contended that “any process of growth that does not lead to their [basic needs] fulfillment – or, even worse, disrupts them – is a travesty of the idea of development”; the 1975 Dag Hammarskjöld Report (p. 27) which contributed the notion that meeting physical needs allows people the ability to fulfill social needs, such that “the basic needs of men emerge as social needs”; the Latin American World Model (Herrera et al. 1976) which constructed a mathematical model of how developing countries could satisfy their citizens’ basic needs without endangering environmental sustainability, acting as a direct challenge to the Club of Rome’s *Limits to Growth* that fulfilling basic needs was primarily a sociopolitical challenge rather than an environmental one; and the ILO’s report for the 1976 World Employment Conference which marked a dramatic shift from promoting growth-led development strategies to explicitly proposing that each country adopt a BNA that included not only physical needs but access to public services, employment with appropriate pay, environmental quality, and participatory governance. The ILO report was particularly noteworthy in part because of its foundation of country studies across developing regions of the world and from its political acceptance. At the 1976 World Employment Conference, 121 governments agreed to this new framework, albeit with significant reservations from both developed and developing countries.

By 1978, the World Bank, ILO, UNEP, UNICEF, and USAID were the chief proponents of the BNA among development organizations with Latin American governments providing the chief political support from developing countries (ODI 1978). During the 1980s and 1990s, however, the BNA suffered significant setbacks. Recessions in Latin America reduced those governments’ ability to fight for basic needs at home and abroad. The rise of the Washington Consensus refocused development thinking on more growth-oriented policies through political retrenchment. In addition, new intellectual challenges emerged from within the community of scholars that had been most likely to support

BNA, such as Amartya Sen’s capabilities approach and the human rights framework.

Criticism focused on a handful of challenges in applying BNA (Rudra 2009). The primary concern was the lack of agreement among scholars on which needs were basic. The core basic needs group focused on a minimal set of needs essential for sustaining life. This core principally included food, shelter, water and sanitation, education, and health and sometimes included employment or political participation. The expanding basic needs group, in contrast, believed that human development should focus on ensuring individual well-being and recognized that once one need was satisfied, additional needs came to the fore. Rather than ensuring a minimum lifestyle, the real goal was nothing less than the full physical, mental, emotional, and social development of all people, with lists of needs that included “democracy, marriage, recreation, religion, and furniture” (Rudra 2009, p. 134; see also de Campos 2012). Among the latter group are the World Health Organization, which defines health as “a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity,” and the UN’s Universal Declaration of Human Rights (UDHR), which states in Article 25.1 that “everyone has the right to a standard of living adequate for the health and well-being of himself and of his family” (De Campos 2012). The World Bank, ILO, USAID, and most governments tended to favor the former group, preferring a smaller set of clearly identifiable targets, limited political accountability, and finite budgetary expenditures.

In addition to disagreement on which needs were basic, there was quantitative disagreement over how much of any particular need was basic and how to deal with the generally accepted fact that different people require different amounts of these basic needs at different times and places depending on a range of factors (Reader 2006). Cultural differences add to this complexity. While part of the moral appeal of the BNA is that these human needs are universal, many of them may differ in form or quantity across societies or over time. Examples include different caloric needs depending on lifestyle and different food choices depending on culture, different shelter

requirements based on climate, different perceived social needs by gender or age, and different perception of the relative worth and necessity of different needs depending on cultural factors. This lack of agreement on focus and the challenge to be simultaneously universal and sensitive to local differences reduced the BNA movement's policy relevance and made it easier for other conceptualizations of human development to gain prominence.

Despite the theoretical schism between the minimum basic needs and expanding basic needs camps, in practice measures of basic needs focused on easily measurable baskets of minimally necessary commodities. Often, the commodities were not only measurable but monetizable, making it possible to construct cost of basic needs (CBN) poverty lines as the United States did in the 1960s (Chambers 1982; Arndt and Simler 2010). Sen (1984) criticized this as "commodity fetishism," insisting that freedom was a basic need in itself for human development. If participants do not have the freedom to voice their own needs, it was argued that BNA was too patronizing and incomplete (Sen 1984; Rudra 2009). Reader (2006, p. 338) indicates that "the emphasis on the 'basicness' of needs caused offence, suggesting helper-groups believed poor people 'really need' water, but do not 'really need' goods subserving other dimensions of human life like religion or relationships."

The BNA has had a resurgence since the Human Development Index (discussed below) and the Millennium Development Goals (MDGs) were established by the United Nations in 2000. As the culmination of over a decade of international conferences on human development, the MDGs represented a significant consensus on what needs were considered basic across the world and how to measure them. The presence and signatory support of most governments served to weaken the criticism that developing people did not have a voice in the process. There has been a marked increase in attention paid to fulfilling the basic needs embodied in the MDGs and whether or not economic growth and development assistance were successfully fulfilling those basic needs. Alkire (2005) notes, however,

that the MDGs relate to states of being or functionings people need (avoiding premature death and chronic hunger) rather than the intermediate goods/capacities people need in order to achieve those states of being as Wiggins (1998) lays out.

In Comparison

While basic needs are most likely to be advocated as a measure of absolute poverty, there is no *a priori* reason that one's basic needs might not be relative to what other members of society have. Needs are likely to become increasingly relative as average incomes rise and as needs take on increasingly social dimensions. For instance, the physiological need for a particular number of calories is an absolute need, while the need for types of food that are culturally appropriate depends heavily on the surrounding culture by definition.

There are three primary methods for measuring poverty that may significantly overlap the BNA. These are the monetary, capabilities, and human rights approaches. Monetary poverty lines based on the cost of obtaining basic needs (CBN) can follow much of the spirit of the BNA while focusing more on the means people have to meet their basic needs than on their actual fulfillment. Constructing CBN monetary poverty lines requires a number of assumptions that BNA purists would find rather strong, such as placing specific monetary values on a year of life or the probability a child will die, valuing purchased inputs to health processes that are sold in markets rather than the experience of being healthy which is not, and ignoring basic needs that have neither marketable price nor reliable shadow price estimates. On the other hand, most BNA measures of poverty must make similar judgment calls in order to construct a composite index and lack the theoretical rigor that market prices provide. As one example, Guruswamy and Abraham (2006) construct a CBN poverty line based on the cost of obtaining certain basic needs in India: nutrition; basic health measured as the expected value of healthcare expenditure, clothing, and miscellaneous; and access to water and sanitation, shelter, education, electricity, and roads. Looking at just

the monetary aspects, that would create a poverty line of Rs. 840 per capita per month. They find that 85% of rural Indians and 42% of urban Indians fall below that line, significantly more than official poverty figures.

As in the BNA, Sen's capabilities approach examines a large set of basic needs, but the primary emphasis in the capabilities approach is on whether or not a person has the capability to fulfill a needed functioning rather than whether the need is actually fulfilled in practice. The focus is on means rather than ends and on the individual freedom to choose whether or not to fulfill those ends are the key distinctions. Survey work in South Africa finds that while both utility- and BNA-derived poverty measures do not provide a sufficiently broad space to cover what individuals actually conceive of as their needs, there is at the same time a more significant overlap between the three approaches than adherents of the capabilities approach normally suggest (Clark 2005). Reader (2006) provides a vigorous defense against many of the criticisms of BNA brought up by capabilities approach proponents. Since fulfilling people's basic needs has a moral force that "acquiring capabilities" cannot have, the replacement of BNA with the capabilities approach may have been premature (Alkire 2005; Braybrooke 2006; Rudra 2009). Wiggins (1998) argues that the word "need" itself has a special meaning that implies some things are required regardless of what one chooses, reducing the moral necessity of the capability approach's focus on freedom. Alkire (2005) attempts to merge BNA with capabilities and the MDGs, producing a notion of basic needs capabilities.

Stewart (1989) argues that the human rights approach evolved in parallel to the BNA, though the work was done by different agents from different disciplines to create separate conceptual frameworks and policy spaces. The 1976 International Covenant on Economic, Social and Cultural Rights established that most of the core basic needs were also human rights. As very similar approaches from the outset, they shared many of the same strengths and criticisms, particularly over which needs are rights and to how much of a needed commodity or functioning one has a

right. The rights dimension adds several important concepts absent from BNA. Most important is the notion that for every right holder, there is also a duty bearer who must fulfill the right, while there is no such legally recognized "needs provider" in BNA. Thus, declaring something, a human right adds a greater sense of obligation to governments as the entity most likely to be declared the duty bearer. The right to human development brings the concept of rights well beyond the core basic needs into the realm of expanding needs.

Applications

One of the greatest challenges in applying the BNA is dealing with the inherently multi-dimensional nature of poverty. Numerous papers have described the theoretical problems that need to receive greater attention across multi-dimensional poverty approaches (e.g., Thorbecke 2005). When practitioners gather information on dozens of basic needs indicators, they need a simple means of combining them that is informationally relevant yet readily comprehensible for policy makers and the general public. Any and all attempts at doing so, however, are by nature ad hoc and involve making strong ethical and statistical assumptions that are difficult to defend. Following are brief summaries of some of the more prominent attempts at actualizing the BNA and a brief comment on how well each embodies the main goals of the BNA.

The UNDP's Human Development Report was begun in 1990 with the express aim of pushing back against the Washington Consensus using the BNA and capabilities approach fostered by its founding editors (e.g., Paul Streeten and Frances Stewart for BNA; Amartya Sen for capabilities). The Human Development Index (HDI) constructed by the UNDP (1990–2013) (hdr.undp.org) combines countries' ranks in educational attainment and life expectancy with their per capita GNI. Before 2010, the HDI combined the three measures by finding the mean of the three scores. After 2010, they were combined geometrically instead. This change significantly increased the weight on the lowest score of the

three and reduced the substitutability between the three dimensions of development which were seen as improvements in the methodology. However, it also created other unusual ethical assumptions, such as that the monetary value of an extra year of life in a country like Zimbabwe went from being 1/70th of the value of an extra year of life in the United States to being valued only 1/17,000th (Ravallion 2010a). Across countries, the weight of longevity and education has significantly decreased for most countries, putting greater focus on income, which may not have been the intention and has certainly brought the HDI further from BNA ideals. The HDI has also tended to more closely follow the capabilities approach manner of thinking of about the possibilities people have using aggregated national data rather than on the results individuals face.

At least 13 Latin American countries use a form of unmet basic needs index (NBI) to measure poverty and identify where greater expenditures and intervention are needed. The modal country uses five indicators. The four factors most countries have in common are: crowding, access to sanitation, access to safe water, and school attendance (Hicks 1998). The dependency ratio, the education level of the household head, housing quality, illiteracy, access to electricity, and malnutrition are also popular indicators. These indicators are generally chosen based on their availability in population census data. The World Bank's Poverty Assessments and Poverty Reduction Strategy Papers have also typically drawn on multiple basic needs dimensions, though relying on them to varying degrees and making limited explicit use of BNA terminology and theory.

The Multidimensional Poverty Index (MPI) was developed for the same UNDP Human Development Report that altered the HDI (Alkire and Santos 2010). Multiple indicators of the standard of living (six), health (two), and education (two) are combined into a ten-item index, eight of which directly correlate with MDGs. Households are classified as poor if they are deprived in at least three of the ten indicators. The MPI's greatest strength lies in its ability to identify patterns of poverty – clusters of unfulfilled basic needs that are correlated with each other within a population

subgroup – to enable decision makers to target interventions to address those specific patterns. However, by giving each basic need equal weight, the MPI implicitly argues that the death of a child in the family is morally equivalent to having a dirt floor or owning a radio while lacking a telephone or a mode of transportation.

Ravallion (2010b) provides a thorough critique of the MPI and of similar poverty measures that aggregate deprivations. He mostly defends the notion that multidimensional poverty work should avoid making single “mash-up” indices that combine all the dimensions into a single number, preferring the “dashboard” method because it is in general the joint distribution of those shortfalls that are of interest. He also notes, however, that poverty lines generated from household consumption based on hundreds, or in some cases thousands, of items are multidimensional even though they are typically called unidimensional. Ravallion (2010b) further notes that while using market prices relates the poverty measure to human choice and human welfare, the aggregation weights assigned by researchers do not reflect local choices and are rarely updated. Particularly from a policy standpoint, it is important to differentiate between ends and means. For instance, people have a basic need for food and nutrition; access to some form of food stamp program may be one means to ensure people are able to fulfill their basic need for food, but lack of access to food stamps is not itself an indicator of poverty. Hicks (1998) debates whether access to water and sanitation are needs in themselves or merely means to the end of health and whether access to education is a need or merely a means to the end of literacy. Hicks (1998) also warns against using indicators of poverty that correlate too closely with income to ensure that each indicator provides useful, independent information.

Summary

The basic needs approach was designed to focus greater attention on nonmonetary aspects of poverty that are absolute, entrenched needs, vital for human welfare. Though its initial success during

the 1970s was short-lived, a revival has been underway in both theory and application since at least the Millennium Development Goals. It also served as a foundation for the growth of the capabilities approach.

There is still a gap between theory and empirics in BNA. Theory acknowledges a number of difficulties – such as identifying complete sets of basic needs based on local feedback and the difficulty of assigning meaningful weights to each factor – that are often ignored in practice in favor of the exigencies of what data are available and creating single indices that make it easy to communicate simple policy messages. There is much work yet to do to reconcile practice with theory and to combine the insights of the basic needs, capabilities, and rights approaches into a more unified and powerful development paradigm.

Introduction

Western medicine provides the dominant discourse surrounding pregnancy and birth management throughout much of the world, a view endorsed by the World Health Organization and countless aid agencies, displacing indigenous understandings of pregnancy and its relationship to food in particular.

Until the 1960s, Western medicine viewed the pregnant woman as a body with an insulated, parasitic capsule growing inside it. The capsule within was seen as virtually omniscient and omnipotent, knowing exactly what it needed from its mother-host, reaching out and taking it from her – taking vitamins, minerals, protein, and energy, at her expense if necessary – while protected from all that was bad or harmful.

The pregnancy in this model was almost entirely a mechanical event in the mother, who differed from the nonpregnant woman only by the presence of this thing growing inside her. Differences other than mechanical changes, such as the enlarging of the uterus, were accordingly seen by physicians as symptoms to be treated so that the woman could be kept as “normal” as possible throughout the “stress” of pregnancy. (For a discussion of the medical and midwifery models, see Rothman 1982; Simonds and Rothman 2007.)

Working with this model, obstetricians did not consider pregnancy as necessarily unhealthy, but pregnancy is frequently associated with changes other than the mechanical growth of the uterus and its contents: these changes the doctors *did* see as unhealthy. For example, the hemoglobin count,

which is lower in pregnant women than in non-pregnant women, makes pregnant women appear (by nonpregnant standards) to be anemic. The result was that doctors treated this anemia with iron supplementation. Water retention, or edema, is greater in pregnant than in nonpregnant women. Obstetricians treated this “condition” by placing limits on salt intake and prescribing diuretics. Pregnant women tend to gain weight in addition to that accounted for by the fetus, placenta, and amniotic fluid. American obstetricians then treated women for this weight gain by putting them on strict diets and sometimes prescribing “diet pills.” Knowing that these changes were very likely to occur in pregnant women, American doctors set out to treat all pregnant women with iron supplements, limits on salt and calorie intake, and diuretics, all in the name of “preventative medicine.”

With the advent of thalidomide, a drug obstetricians prescribed for morning sickness, that passed through the placenta and caused dramatic limb reduction birth defects, an epidemic of “German measles,” and the observable fetal consequences of radiation exposure following the bombing of Hiroshima and Nagasaki, the image of a protected fetal parasite was no longer tenable. The fetus is now understood as a vulnerable “patient” trapped within the confines of the woman’s body.

Medicalization of Women’s Lives

Bordo (2003) argues that the surveillance of women’s eating and drinking preferences during pregnancy is an inevitable flow from the medicalization of women’s health in life more generally. From a Foucauldian perspective the moment a pregnant woman steps into the hands of the health professionals, the disciplinary gaze and surveillance of her nutritional status and control over her pregnant body commences. Weight gain, the most obvious indicator of food consumption, comes under immediate medical scrutiny. During the first antenatal visit, the pregnant woman is usually weighed and her weight gain monitored throughout the pregnancy. Weight gain guidelines shift

dramatically across time: In the earlier “insulated capsule” model of pregnancy, weight gain was expected to be limited to the actual weight of the fetus, placenta, and amniotic fluid, and women were reproached for additional weight gain. The switch to the “vulnerable fetus” loosened those guidelines and permitted women to – as appears to be biologically normal for women with access to adequate nutrition – gain extra weight, perhaps in storage for prolonged lactation. The current focus on the “obesity epidemic” brings back more stringent weight gain guidelines. While all women, and indeed all citizens, in the Foucauldian sense, are subject to the medical gaze and the health imperative, this has proved particularly problematic in pregnancy.

From a philosophical perspective, matters of health are sometimes found to be in conflict with values such as freedom or autonomy. If health is understood as being extrinsically valuable, people should be able to sacrifice health as we please without any moral justification. However, if health has an intrinsic value (that we should not cause unnecessary damage to self or others), then it could be considered wrong for a woman to behave in a way that may cause harm to her unborn baby.

Critics have suggested that medicalization has become a cliché of critical social analysis. However, the application of this theory to the subject of food is persuasive, and this is particularly so when pregnancy is considered. Women are burdened with information about diet during pregnancy, and much of it is negatively focused on avoiding pathological conditions such as food-borne infections. There is little that extols the health benefits for both women and their babies of taking a health-based approach to eating during pregnancy. In the medical model, the woman is seen as essentially a barrier to fetal care, and her food choices understood primarily in terms of fetal risk.

An appropriate analogy may be that pregnant women are like players in a real-life snakes and ladders game where if they do the right thing – e.g., avoid soft cheese/stay within a reasonable weight gain limit/eat no more than one portion of tuna a week – they can climb up the ladder, but if they do the wrong thing, e.g., eat chilled

prepared foods or drink one glass of alcohol, they will slide down the snake and be viewed through the lens of the medical world with concern. In fact the scrutiny would seem to extend far beyond the medical gaze, with the media reporting stories of women perceived to be pregnant by cabin crew on airlines, being refused a requested glass of wine in flight. Yet dietary advice is far from being a constant or consistent form of knowledge but is consistently altered to reflect the changing evidence as reported in the media. One year it is the potato that must be avoided, another year it is peanuts. One year the concern is with fats, another it is with sugars. While all citizens are subjected to this information flux, pregnancy is a uniquely time-bound experience: If this is the year that tuna is switched from the good list to the bad list, and this is the year one is pregnant, one faces the potential of lifelong damage inflicted on one's baby.

Food Rules and Social Control

Food rules and taboos in pregnancy are not at all unique to the modern world of course and can be found across temporal space and cultural boundaries. For centuries Western women have been encouraged to eat for two, to avoid spicy foods, and to follow their instinct for cravings (*pica*) including eating clay and coal (*geophagia*). In much of the Eastern world, women are expected to adhere to the cultural practice of balancing "hot and cold" foods and observing those and additional specific food practices while "doing the month" following childbirth. In parts of Africa, cultural taboos discourage women from eating specific fruits and vegetables during pregnancy. There are ritual fasts and ritual feasting during pregnancy found around the world. Pregnant women everywhere and always are subjected to larger social forces than their own unique embodied experiences and appetites. Such is the nature of human life – humans are social beings. What switches over time and space is who holds the authoritative voice, and in the contemporary world, that is biomedicine.

With more space, one could usefully trace the tales of specific foods that have moved in and out

of acceptance as appropriate or dangerous for pregnant women: potatoes, tuna, peanuts, red meat, fats, and more, as already alluded to. Here is one specific enduring example of a Western pregnancy food-related taboo and then a turn to the more general issues of *amounts* of food rather than specific food items.

The specific example is alcohol: There is good evidence that women who are alcoholics, eating the nutritionally poor diet typical of alcoholism and drinking large amounts of alcohol on a regular basis, can indeed birth babies with what is known as "Fetal Alcohol Syndrome," or FAS. What there is not is evidence that occasional or what is known as "social drinking" has negative fetal consequences. But with the discovery of FAS, alcohol became entirely taboo for pregnant women in the USA, and its path from a research finding to a state-endorsed social policy is itself a fascinating story (see Armstrong 2003). Without supportive data, women who reached for a glass of wine with dinner, who sipped a beer at a party, were subject to formal and informal social sanctions: denied service in public places, reproached by friends and family. Pregnancy warnings appeared on bottles and on restaurant walls. Refusing a drink became one of the earliest public signs of pregnancy, and having any amount of alcohol while visibly pregnant made a woman subject to sometimes extreme approbation and even threats of social services removing the child from her custody at birth. This particular pregnancy taboo built on the long and uniquely fraught history of alcohol in American public policy; the potential risks of peanuts or tuna could not have achieved such public acknowledgement and endorsement so quickly.

The information that people in Western societies receive concerning what constitutes a good diet in pregnancy is certainly influenced by the food industry, which has its own agenda and is, to this point, less regulated and less suspect than the alcohol industry. So who are pregnant women to trust when it comes to advice relating to what to eat and drink during pregnancy? Far from feeling safe and well informed, it would seem that pregnant women find themselves lost and confused in the dietary maze, as specific foods move in and out of favor.

Too Much or Too Little? The Two Sides of Malnourishment

It is more than ironic that at a point in history where obesity is being flagged as the number one nutritional issue in the world, it is estimated that there are over 800 million hungry people in the world. It would seem that those of us in high-resource-use countries are struggling to keep food energy consumption under control, while in low-resource-use countries, particularly those in sub-Saharan Africa, many are finding it difficult to sustain their nutritional needs and in too many cases are starving. According to the World Bank, 36 countries, mostly in sub-Saharan Africa, are in a food security crisis. This means that globally many millions of women are likely to be grossly malnourished during pregnancy, the major contributor to poor outcomes in terms of both maternal and perinatal mortality. While there is of course food aid, its public face is the hungry baby or child – the pregnant woman is largely absent in the portrayal of world hunger though arguably hunger has its greatest consequences in pregnancy.

Pregnancy and birth are now known to be extremely energy demanding processes with the ingestion of food a crucial part of this process. An increasing body of knowledge around the importance of good nutrition during pregnancy now suggests the adage “you are what you eat” should be “you are what your mother ate.” Diet during pregnancy can have lifelong consequences for the fetus.

There is little doubt that a nutritionally rich diet with a sensible balance of both macro- and micronutrients offers the best possible start in life. Micronutrients in particular may hold the key to protecting the developing fetus from the effects of exposure to toxic chemicals including teratogens and carcinogens. Suboptimal nutrition may additionally adversely affect the growth of the fetus, and impaired fetal growth is associated with increased perinatal morbidity and mortality as well as infant mortality and childhood morbidity. Studies as early as the post-WWII Dutch Famine Study have demonstrated that pregnant women subjected to food shortage

appear to produce babies who are more likely over the life course to develop diabetes, obesity, and cardiovascular disease and experience other health-related problems. What pregnant women eat has long-term potential for health and well-being and has impacts far beyond the period of childhood.

The focus in the developing world regarding pregnancy however has largely been on replacing indigenous childbirth practices with Western-trained practitioners, with far too little attention to the needs of pregnant women over the course of the pregnancy and even less into the prepregnant time. If poor nutrition has such easily demonstrable consequences for maternal and infant outcome, from simple survival to healthy adulthood, it would seem reasonable to suppose that the most effective way of avoiding less than positive outcomes would be to ensure that all women were supported in accessing the best possible dietary intake during pregnancy, in the form of good information, education, and where necessary practical help.

What should not ensue is a “mother blame” approach that reproaches women for eating poorly and placing their babies/children at risk as a result. However, some of the issues arising from the areas of food and diet in pregnancy could be construed as adding additional pressure around what women “should” eat and what they “should” not eat. There is an abundance of evidence that shows that heightened anxiety can increase the stress load for women within pregnancy, bringing a further threat of potential insult for the fetus in the form of increased catecholamines and cortisol levels. These can lead to permanent metabolic and endocrine changes influencing health throughout life. This is especially the case where some pregnant women live in poverty and access to nutritious foods is limited or even nonexistent.

Mother blame is most obvious in the other side of the malnutrition dilemma: obesity. The issue of obesity, weight gain, and pregnancy within a conventional weight-based paradigm has attracted enormous attention in recent years. Pregnant women using maternity services receive clear messages that if they are obese, they have a

greater risk of developing a range of complications in pregnancy and childbirth. Obesity has become increasingly medicalized, with its relationship to poor infant outcome often misstated as a *cause* rather than a *correlation*. These “authoritative” accounts often contain overstated claims about the damaging effects of body fat on the health of pregnant women and their babies. Increasingly, health professionals are taught to view obese women as “a statistic waiting to happen.” Not all obese women will present as problematic; the degree of risk will vary with differences between a well-nourished and an undernourished pregnant woman, and weight/fat alone does not capture that distinction.

There is certainly a lack of knowledge among health professionals of the social, psychological, and economical effects that influence obesity as well as personal well-being. This knowledge deficit adversely influences access to maternity services, quality of care, health equity, and outcomes of care, for women who are more vulnerable and disadvantaged.

The very measure of obesity is complicated in pregnancy: Body mass index has been commonly used as a definition that measures too much body fat in pregnant women. Its use is highly contentious. BMI is a height to weight ratio used to measure the “medically defined” condition of “obesity.” In this, a healthy body weight is based on a measure of body fat that falls within a numerical range of 18.5–25. However, this measure has been criticized by both social and medical scientists. It is not consistently applied because there is disagreement among medical practitioners as to what optimum body weight actually is. This has resulted in disagreement on whether obesity should instead be measured by waist circumference although this would seem rather absurd for pregnant women given their growing waist lines.

“Obesing” and fixating on the size of pregnant women’s bodies can detract attention from other areas of their lives where they may benefit from additional support. Fat activists have pointed out that a raised BMI alone does not necessarily constitute a threat if the woman is well nourished and is able to access good levels

of support. In contrast, the woman with a BMI which sits within the “accepted” range but is undernourished and does not have a good support network in place may be totally overlooked. By focusing on alleged “risk” factors such as BMI, it is possible that health professionals are missing the big picture and making broad generalizations which are all too often translated into judgment about overweight women (Wray and Deery 2008).

The media, health professionals, and general public leap to groundless conclusions that any possible health risks (e.g., hypertension, diabetes, heart disease, and cancers) are *caused* by obesity. Other legitimate forms of evidence simply do not enter into the public domain for discussion and debate; the risks of obesity are asserted without reference to work that demonstrates otherwise or questions the credibility of the findings. This situation has created a powerful and pervasive discourse where the health risks associated with obesity are often communicated as scientifically based fact and obesity is viewed as a dangerous disease. Global obesity pandemics are increasingly referred to, and the dietary habits of Western societies are now being blamed for increasing obesity rates in developing countries.

As well as having health issues blamed on their body size, obese pregnant women are also more likely, than their counterparts, to receive judgmental comments from members of the health professions. When a more accepting and supportive approach to obesity by health professionals does not happen, social discrimination, stereotyping, and stigmatization occur much more frequently. When these negative social responses come into play, the effect on pregnant women is easily ignored or forgotten, and women are judged on the basis of their size and appearance. Internalized views and opinions about “obesity” can easily be transmitted subliminally to women and their families increasing the potential for marginalization and lack of uptake of health services, and so the negative attitudes about obesity itself can cause problems (Deery 2011).

A consensus seems to have emerged in the world of scientific research that has not yet made

it into medical practice or social awareness, that being obese is associated with a broad range of social, psychological, and economical effects on a pregnant woman's life. At the same time the failure of the conventional weight-based paradigm has led to a greater consideration of possible risk factors that appear to be correlated with obesity. These include psychological factors, eating patterns, activity levels, family background, and amount of sleep. Associated with discrimination and stigmatization, obese people may externalize a sense of guilt, possibly leading to more negative experiences with health care, a situation exacerbated by pregnancy.

Alternatives to Medicalization

Biomedical reductionism is still the dominant paradigmatic approach in maternity care, with little time or attention paid to a more holistic perspective. In addition and not unrelated, there is an increasingly market-driven approach to maternity care.

Women-centered care following the precepts of the Midwifery Model of Care offers an alternative. In this approach, the individual needs of the woman are assessed and a plan negotiated between the woman and the midwife that enables her to meet her specific needs to optimize the health and well-being of both herself and her baby during pregnancy. Rather than seeing mother and fetus as separate individuals in a potential conflict, midwifery care sees the two as an interconnected whole. Improving the health of the mother, through nutrition as well as other support, is seen as the best way to care for the baby.

During pregnancy women may be more receptive and open to education about food, health, and well-being. For the first time they may have a sense of their own place in the universe and see a generation ahead. This is a time when further understanding about nutrition and the importance of micronutrients would be useful. Although some midwives have a strong focus on nutrition in pregnancy and can help to educate and navigate women to a healthier or

more tailored diet, many midwives – especially those medically trained and in medical settings, such as is the case among many UK midwives and many American nurse-midwives – are actually poorly equipped to assist women to optimize their nutrition during pregnancy. This can be seen to result in a population-based approach to the “management” of nutrition in pregnancy, where women are encouraged to accept a prescriptive one-size-fits-all approach to food and diet which is centered on food safety issues and supplementation of micronutrients.

Supplementing women in pregnancy with a variety of micronutrients from folic acid, vitamin D, and iodine is now common in maternity settings worldwide. However, there is no agreement about what constitutes the correct dosage, when the supplementation should begin, whether it is really necessary, and what are the associated risks of any given form of supplementation. This universal approach may give the message to women that “you are not capable of eating well enough to provide all that your baby needs to grow and develop effectively and here is a medicalized solution in the form of a tablet.” The practice has led to a growing “nutraceutical” market. The food/pharmaceutical industry has recognized this and has effectively constructed a niche market. The advertising images are of healthy glowing pregnant women as a result of taking multivitamins, which may be largely unnecessary if the woman was taking a well-balanced and nutritional diet. The power to create a healthy baby is thus moved from the actions of the mother to medicalization.

There is not in the midwifery model a sense that the needs or desires of the mother must be sacrificed for the good of the fetus or that the mother would indeed have needs that are other than good for the fetus. For example, midwives repeatedly state that if the mother gives up “junk food” and eats better food for the baby's sake (less refined, more “natural” foods), the mother will feel better and healthier. There has always been much talk in midwifery and alternative-birth circles about a woman “getting in touch with her body.” That makes sense only if pregnancy is viewed as a normal condition of the female

body. The introspection, the psychological turning inward and self-absorption which may accompany pregnancy, is seen as an opportunity for the woman to learn more about her body and its needs and rhythms. A woman's pregnant body is still very much her own in this model and is not a host to a parasite. Where the medical model sees pregnancy as a stress and a drain on the mother, the midwifery model sees it as a period of physical and emotional growth and development for both mother and fetus.

While medicine attempts to maintain the normalcy of the mother throughout the stress of the pregnancy, viewing deviations from normal (nonpregnant) status as symptoms of disease states, midwifery views the changes as demonstrating the health of the mother. Rather than seeking to change the mother back in the direction of nonpregnant normality, midwifery's goal was to provide the best possible environment in which the changes of pregnancy could occur.

In the medical model, prenatal care is the *management* of pregnancy, like the medical management of any (other) disease. Nutrition is not much valued in medical care in general and understood more in terms of risk than of health. Even now the "prenatal care" that obstetricians offer women is basically a screening program. The visits typically take 10–15 min or less, in which the woman is weighed, her blood pressure taken, and her urine tested. Blood is drawn for yet more screening and testing. She lies on an examination table, and the fetal heart rate is noted, as is the position of the baby. If she has symptoms to present, these are noted, and remedies may be prescribed. As is often the case in physician visits, a prescription handed over is a way of resolving questions and terminating the interview. As heretical as it may sound, it is hard to find any evidence that prenatal care improves birth outcomes.

Midwifery care offers a more individualized, culturally competent and specific, nutritionally thoughtful approach, with demonstrably better outcomes. How much of that difference is due to nutrition, and how much to other aspects of midwifery care is yet to be determined.

Summary

Pregnancy has become deeply medicalized, and in dominant medical discourse pregnant women and their behavior are understood primarily as risks to their contained fetus. As such, issues of nutrition and feeding in pregnancy, including food scarcity and obesity as well as specific food taboos, are increasingly understood and controlled through medicine. Midwifery offers an alternative interconnected approach, encouraging healthy eating in the interests of the mother-fetus dyad.

Introduction

This entry focuses on food production, food security, and food sustainability through the lens of rural schools and, in particular, establishing schools with an explicit primary industries entrepreneurial orientation. The practice and policy context for the entry is Australia which has points of differentiation when compared to most other countries, in particular a very large land area, a small population, and a low population density. Notwithstanding, there are ways to generalize from the specificity of the Australian context, including by reference to the widely accepted role and function of schools in societies, namely, educating young people to be responsible, productive, and contributing citizens, and through a set of principles for progressing an ethics of sustainability.

Ensuring that Australia (and all other countries) is food secure should not be taken for granted. As Australia's population grows and changes over time and the impacts of climate change "kick in," new problems and opportunities will emerge. These changes, and others that food production and distribution are reliant on, provide new policy development and program opportunities for rural education, rural educators, and rural communities.

One of the common characteristics of rural communities globally, and especially those in the developed countries of the world, is the exodus of

youth in search of "greener pastures." From research undertaken in Australia which is helpful to illuminating similar issues in other countries, Alston and Kent (2003) argue that "[t]he lack of meaningful full-time work in rural areas is one of the main reasons for young people leaving rural communities." Limited post-secondary education and training is another significant reason for the exodus of youth from rural areas. Often added to this is a gender imbalance, where young females leave rural areas at a higher rate than young males. There are also challenges associated with the education of indigenous youth, so they have choices about their cultural identity, employment opportunities, and personal fulfillment.

A primary industries entrepreneurial orientation to education and an ethics of food security and sustainability bring together critical matters of choice with regard to purpose, and principally moral purpose, and taking action to "do what is right, to do what is required" in the light of overwhelming evidence. Food production, distribution, and security challenges confronting the globe underpinned by unprecedented population growth rates are an instance of overwhelming evidence for "doing business differently." Kurlansky's deeply insightful and disturbing book on the biography of the cod and its demise overtime – "abundance turned to scarcity through determined short sightedness" (1997) – epitomizes how a sustainable resource has been pushed to the brink of extinction by an absence of an ethics of sustainability to inform and govern choices. Put another way, "in a very fundamental sense, we are what we pay attention to... Our attention is precious and what we choose to focus it on has enormous consequences" (Fleischner 2011).

Context and Dimensions

Australia comprises six states and two territories, each of which has an elected parliament as well as a national government. It has a population of nearly 24 million, the majority of who live in the three most populous states – New South Wales, Victoria, and Queensland – and a land mass of

7.5 million square kilometers. Distance and very low population density are two of the dominant challenges of ensuring all children can access schooling. Under the Constitution, the states and territories are essentially responsible for providing and managing schools. In recent years though, the national government has played an increasingly important role in education, principally through its financial powers and by developing coalitions of support for initiatives like the Australian Curriculum, the public release of school performance data, and literacy and numeracy testing.

According to the Australian Bureau of Statistics (2014), there are nearly 9,400 schools in Australia for 3.6 million full-time equivalent students from preschool to year 12. As well, there are three main schooling sectors – government (6,651 schools), catholic (1,722 schools), and independent (1,016 schools). Definitions of a rural school vary by jurisdiction and by sector. However, around 40–50 % of schools are in nonurban locations in communities which vary in size from about 100,000 to less than 100. In some locations, schools are literally in the corner of a farmer's paddock. Most rural schools are government because governments are required by legislation to ensure children can access education. As well, most rural schools are in close proximity to primary industries and, in some instances, have direct engagement with primary industries through agriculture topics and farm practices, aquaculture projects, and courses which provide support services for primary industry enterprises like technology studies and economics. There are also urban schools which have a direct link with food production through curriculum specializations, school and community vegetable plots, and farmers' markets.

Rural contexts have evolved and changed over time and will continue to do so. Looking forward, there will need to be "an openness to ruralities that are quite different from those we are familiar with" (Cocklin and Dibden 2005). The capacity to accelerate the speed at which the evolution and change of rural contexts occurs has been dramatically increased through globalization – especially via ICT, interconnectedness, acceleration,

disembedding, and standardization (Eriksen 2007) – and through the continued growth of the world's population. The pressures these place upon the ways a community functions and on the environment, finite resources, and relationships at a multitude of levels are profoundly significant. The changes require – demand – a radical reframing of the role rural education and rural communities might play in nation building and nation sustaining through food production and food security.

Food

Food production and security are inextricably linked to the principal social, political, economic, and cultural dimensions of a society and particularly to environmental health, well-being, and sustainability because of the fundamental connection between nature and food. Flannery argues that "[o]ur search for sustainability ...[is] the greatest challenge we have ever faced" (Flannery 2008). Pretty's focus on sustainability and agriculture foregrounds human activity as central to the understandings of it and highlights "not damaging the environment" (Pretty 2002). Goldie, Douglas, and Furnass draw upon the Brundtland Report of 1987 for their definition of sustainability, "the capacity of human systems to provide for the full range of human concerns in the long term" (Goldie et al. 2005). Their definition accentuates imperatives for survival.

Food production and food security are not discretionary items of national policy or of national productivity. As Pretty argues, "[w]ithout food, we are clearly nothing. It is not a lifestyle or add-on fashion statement. The choices we make about food affect both us, intrinsically, and nature, extrinsically. In effect, we eat the view and consume the landscape. Nature is amended and reshaped through our connections-both for good and bad" (Pretty 2002). Put another way, "will there be sufficient nutritious food available for nine billion people by the year 2050?" (Persley and Blight 2008). The majority of the food consumed daily in Australia is produced in rural areas. To illustrate, the Murray-Darling Basin,

while comprising only 14 % of Australia's land-mass, supports around 40 % of Australia's farms (ABS 2012). Producing food, even where it has "gone the way of high tech," still requires large numbers of highly skilled and semiskilled workers. Unlike mining, agriculture and horticulture are not as conducive to a fly-in/fly-out model of labor supply, even with the advent of agribusiness. Critically important as well are young people (and others) imbued with a passion for entrepreneurialism.

In Australia according to the National Farmers' Federation (2016), at farm gate, the agricultural sector contributes 3 % to Australia's total gross domestic product (GDP). The estimated gross value of Australian farm production for 2016 is \$A54.4 billion (ABARES 2015). When the vital value-adding processes that food and fiber go through once they leave the farm are added in, along with the value of all the economic activities supporting farm production through farm inputs, agriculture's contribution to the GDP averages out at around 12 % (or \$A155 billion). And much of this value adding comes from entrepreneurial knowledge, skills, and dispositions. In addition, Australian farmers produce almost 93 % of Australia's daily domestic food supply. With the agricultural supply chain, including the affiliated food and fiber industries, there are over 1.6 million jobs in the agricultural sector of the national economy.

Exploring innovative approaches to rural education and food production and security has the potential to build new understandings and practices about them and also arrest, or at least slow, the marginalization of rural education and rural communities in relation to contributing to Australia's future.

Primary Industries Entrepreneurial Schools (PIES)

A key function of education is equipping young people with knowledge, skills, and dispositions to become autonomous, responsible, and productive citizens. In other words, education is critical for developing and nurturing human

agency, and for this Giddens' (1993) description of agency as "the lived-through process of everyday conduct" is particularly apt. From the perspective of ongoing vibrant and productive rural contexts, a major question flowing from the function of education as stated is, so what might these imperatives mean for rural youth, their learning, and their mobility? What new opportunities are inherent in the challenge of ensuring that the food production capacity of the globe can meet the needs and demands generated by 9–10 billion inhabitants?

Establishing specialist primary industries entrepreneurial schools (PIES) is a way of contributing toward the future demands for high-quality affordable food, addressing some of the drift of rural youth away from their communities, and attracting others to them. Currently most specialist schools in Australia and in other countries are located in cities or large population centers. This is not surprising since enrollments determine resource allocations which in turn drive curriculum diversity and choice. Primary industries entrepreneurial schools, operating either individually or as a cluster of programs, provide a strategic opportunity for doing something very practical to give rural schools and their communities a much needed boost, are a powerful way to provide a better city-country balance, and very importantly, make significant contributions toward food production and food security.

Writing about the US rural context but with relevance for the establishment of PIES, Williams (2004) declared, "[i]f small businesses are the engines of our economy, then entrepreneurs are the sparks that ignite those engines." She then proceeds with reference to other researchers to identify defining characteristics of entrepreneurship education by contrasting it with business education, namely, "business education focuses on managing a business [while] entrepreneurship education focuses on skills needed to organize and start new business ventures." Entrepreneurship curriculum prepares students to:

- Identify or recognize a market opportunity and generate a business plan (service or product) to address the opportunity

- Obtain and commit resources in the face of risk to pursue the opportunity
- Create and sustain a business organization to serve the market opportunity (Williams 2004)

Further, Williams argued:

Recognizing an opportunity may be the most important part of entrepreneurship. . . [and] the challenge for educational institutions is to develop a curriculum within the existing system that provides a decentralized, individualized, and empowering environment in which students can learn or develop the skills needed for entrepreneurship. (2004, emphasis in original)

Entrepreneurship is usually not a linear, step-by-step process. Rather, it is a “mixed bag/mixed methods/mixed opportunities” undertaking that may be very successful but can also result in failure. As Grace (2014) wrote, “failure is always an option; [and] failure provides an opportunity to learn, to regroup and try new approaches, new techniques, call on other experts and to discover new and better solutions.” The European Commission has identified entrepreneurial education as vital to creating opportunities for an expanding population and problematic future. Moreover, it argued that “a dynamic economy, which is innovative and able to create the jobs that are needed, will require a greater number of young people who are willing and able to become entrepreneurs- young people who will launch and successfully develop their own commercial or social ventures, or who will become innovators in the wider organisations in which they work” (2012).

Discussion

Transforming rural schools to become dynamic and effective places for primary industries entrepreneurial education and to be active agents in food production and security, as well as championing ethics of sustainability, are major undertakings. The undertakings fall most directly to school leaders. A prime challenge in tackling this work is preparedness to embrace the pursuit of *Other* (Soja 1996). This requires rural educational leaders spending time creating and seeking

out opportunities that have the potential to disturb, disrupt, and shift the status quo. School leaders can do this in many different ways including by questioning, by influencing meeting agendas, by developing links and alliances within and beyond the school, by moving around and through the school picking up clues, and by making suggestions as to “what might be done instead.” They also need to create and seek out opportunities that will bring about change while, at the same time, projecting a sense of control blended with a preparedness to enter into collaborations with others. As well, they need to draw upon the experiences and advice of colleagues and community and use various ways for reducing multidimensional possibilities into “manageable bits” to progress schooling transformations which contribute to overall deeper engagement with food production and food security.

Leithwood et al. (2004) have argued that educational leaders achieve their impact by paying attention to and working on three “basics of successful leadership. . . setting directions. . . developing people. . . and making [an] organisation work.” Further, of particular relevance to the role and functions of rural educational leaders in terms of primary industries entrepreneurship and food production are understanding context and working with the understandings of context to create something more than, other than, “just a good school.” In the words of the authors, “successful leadership is ‘contingent’ at its roots. . . leaders [require] large repertoires of practices and the capacity to choose from [them] as needed. . .”

As for the “basics of successful leadership,” the authors also identify understanding three dimensions of context as being especially important – “organisation context. . . student population. . . [and] the policy context” (Leithwood et al. 2004). Organizational context includes geographic location, school level and size, and district characteristics such as socioeconomic factors and the like. Student population foregrounds understanding and being responsive to the diversities and commonalities of students including their out-of-school lives. Policy context focuses on a blend of “big picture” directional aspirations such as “world’s best practice”

through to the day-to-day impact of resourcing allocations linked to the state of the economy at various levels. Policy context also highlights a tension – that of providing educational leaders with “certainty, continuity and predictability” about what society or what a community expects of them, while also concurrently managing a change agenda. In other words, a predominant feature of policy context is the dynamic and struggle between issues being bedded down and issues being provisional and temporary.

MacGilchrist et al. (2004) have identified nine intelligences for school improvement and school transformation – “ethical, spiritual, contextual, operational, emotional, collegial, reflective, pedagogical and systemic.” Of particular relevance to PIES and food production are the authors’ definition and perspectives on contextual intelligence. Contextual intelligence “involves the capacity to read, understand and interpret at least four dimensions of the environment in which a school functions – internal, local, national and global.” Appreciating the centrality of contexts and reading them meaningfully and purposefully are integral to the role of an educational leader working in a rural location. Paraphrasing Giles and Morrison (2010), leadership always occurs in context and is always contextualized. The question of how to progress from recognition and reading of context to actualizing leadership “on the ground” can be highly fraught. In recent years, there has been greater emphasis given to leadership that emphasizes the instrumental and technical aspects of formation. What has been downplayed is the potential of leadership in which relationships are pivotal.

Progressing an explicit primary industries entrepreneurial focus through schools requires in addition to identifying leaders and teachers with a passion for entrepreneurial education and providing them with appropriate professional development:

- Finding, growing, and sustaining relationships with local (and other) enterprises and entrepreneurs so that students can access and experience enterprises and entrepreneurship “in real life”

- Linking with post-school training and tertiary institutions such as the Flinders University New Ventures Institute to facilitate career pathways and networking including with venture/start-up capital
- Informing, motivating, and engaging students and their parents/carers
- Focusing on ensuring that three key message systems of schooling (Bernstein 1971) – curriculum, pedagogy, and evaluation – work together productively

Linking rural schools and rural education with food production and food security creates new spaces of opportunity of an intellectual kind as well as a locational and operational kind. It is intellectual in the sense of “pushing the envelope” of the broadly accepted roles and functions of schools in society. It is locational and operational in terms of how the spaces and structures provided for schooling in rural communities – classrooms, specialist learning areas, offices, playing fields, time allocations, and so forth – might be enjoined in the “big project” of food production and food security.

Education is a powerful and pervasive resource for perpetuating and for changing ways of thinking and perceiving, ways of being, and ways of doing and responding. Schools are structured as they are and function as they do, because of a complex mix of legislative requirements, policies, established practices, and expectations about “what schools are and what schools should be.” This “givenness of schools,” however, is constructed and therefore “open” and “available” for change. Put another way, schools *are* because of a long history of decisions, and they would be different than they *are* had different decisions been taken. Or in the words of Lefebvre quoted by Soja, “(t)here is always Other” (Soja 1996).

Principles which frame the global challenge and imperative of sustainability in light of the growing pressures on the planet, primarily through population growth, are also a resource for transforming rural schooling toward explicit primary industries entrepreneurial education and learning about and for food production and food security. Principles “capture” the essences of issues and challenges and

help to scope dimensions and complexities. They can serve as bridging agents between the “big picture” and local contexts and provide indicators of the specific work required in order to change policies and practices. As well, the principles are helpful for evaluating and assessing the characteristics and features of a particular context and then translating them to other situations. They are:

- The sustainability of rural contexts and communities and those who live and work in them is central to sustainability nationally and globally.
- Rural contexts and communities require a productive blend of internal (or endogenous) and external (or exogenous) factors and resources to influence and facilitate sustainability.
- Human services which are available, accessible, affordable, acceptable, and adaptable, at a local community level, are essential for the sustainability of rural contexts and communities.
- Resourcing of human services for rural contexts and communities is an investment in sustainability.
- Sustainability is more likely to be optimized when interconnections between human, natural, institutional, produced, and social forms of capital are recognized and used.
- Sustainability is more likely to be optimized when government funding and accountability requirements are able to flexibly transcend portfolio boundaries.

Using schools as a platform for progressing authentic engagement of students in food production, food security, and the ethics of sustainability requires leaders to work across several change fronts simultaneously and iteratively. This in turn means that rural educational leaders need to know and understand deeply their cultural contexts as stated earlier. They also need to have a sound grasp of the main elements of school operations that, in essence, define what a school is and what sustains the work of a school and indeed that single a school out from all other organizational forms. Of primary importance, here are curriculum, pedagogy, the quality of relationships

with and between students, relationships with parents and community members, concern for standards, and concern for a school’s reputation and credibility. Schools are complex organizations, and processes of change, especially ones that challenge school leaders to step outside conventional ways of functioning, can disturb and disrupt “taken-for-granted” and expected patterns of behavior. During a financial crisis, depositors can lose their trust in banks and withdraw their funds. So too a community can withdraw its support of a school if it is perceived to be not paying attention to its core business – children and their learning.

Implementing any major change of focus in a school, such as the introduction of primary industries entrepreneurial education, is almost guaranteed to generate some resistance, even when the change has been developed and agreed through participatory processes. The senior secondary year levels (years 10, 11, and 12), which are generally considered the high-stakes year levels of schooling, are particularly vulnerable sites for resistance. Resistance can manifest itself in many ways. Attitudes of staff, community leaders, students, and their families and friends which are shaped more by what is “being lost” than what is “there to be gained” is one manifestation. Another is conflict over curriculum and, in addition to new content and assessment processes, different ways of allocating time for students to learn how to become entrepreneurs. Historically, schools have used time in very chunked and rigidly defined ways, most typically represented as lessons. A highly regulated and tightly monitored approach to time as a fundamental resource for learning, especially learning which is heavily reliant on engagement with entrepreneurs and community “outside the school fence in the real world,” is anathema to students gaining the attitudes, knowledge, and skills to become entrepreneurs. In addition, resistance can manifest itself in communications – oral, written, e-based, and pictorial – which explicitly and subtly work over time to shut down or constrain new possibilities “getting off the ground.” In other words, a fear of imaging *other* and letting go pervades thinking and actions.

Lear (2006), in his profoundly insightful book on how the Crow Indians found ways to make life meaningful after their culture was devastated, argued that during times of major change and upheaval, new forms of traditional understandings of concepts are needed. This requires “facing up to reality... [and being prepared] to face up to reality in *new ways*” (emphasis added). Population growth and the impact and potential flowing from it are “*the reality*” that permeates all others. In the west in particular, “*the reality*” is especially germane for rural communities and contexts and the increasing demands that will be placed on them to produce the fundamentals to nurture and sustain the lives of individuals, communities, and societies. Given the seminal role of education in “charting the way” and preparing people for “living *well* with the risks that attend human existence” (Lear 2006), primary industries entrepreneurial schools can make a major contribution to global food production and security.

Summary

Schools and education are used to reinforce values and attitudes about national priorities as well as deal with emerging challenges and problems. Put another way, schools are critical agents for “fixing problems.” Very importantly, they are (or should be) also agents for challenging the status quo and nurturing the young and youth of a society for engaging with and shaping the future, their futures. This entry has briefly considered how rural education and rural schools more particularly might contribute toward food security and an ethics of sustainability. To do this, an outline of primary industries entrepreneurial schools has been presented together with some commentary on implications for educational leaders and schools in rural locations.

Introduction

Food is essential for sustaining the health status of a population. Currently, almost 870 million

people are chronically undernourished, while the number of hungry people remains “unacceptably high” according to the Food and Agriculture Organization (FAO 2012a, p. 8). Yet, already one-third of the earth’s surface and 70% of global extracted water are used for food production (OECD 2010). At the same time, estimates by the World Health Organization (WHO) presently pertain that more than 1.4 billion adults are overweight and 65% of the world’s population live in countries where overweight and obesity kills more people than underweight (WHO 2012). Next to hunger and obesity challenges, an estimated three million people around the world, in developed and developing countries, die every year from food-borne diseases, with millions more becoming sick (Lang and Heasman 2004). Such disease occurrences can easily escalate to a food safety emergency situation, which has the potential to adversely impact national economies and livelihoods and reduce the availability of food for national consumption.

Food provision is often associated with poor working conditions, limited access to social protection, and lack of enforcement of labor legislation (FAO 2012b). Rural labor markets tend to be highly informal, with a prevalence of casual work arrangements and information asymmetries, as well as gender and age-based inequalities (FAO 2012b). Currently, around three billion people work in agriculture mainly in developing countries, with 43% of agricultural labor in these countries being women (FAO 2012a). In least developed countries, the share of the total population economically active in agriculture was 66% in 2009. This accounts to more than double the share of agriculture in GDP (FAO 2012a). Correspondingly to these figures, it is embraced that poverty is concentrated in rural areas since people who work in agriculture tend to have lower incomes. Being at the same time the least organized and least protected by legislative frameworks, rural worker’s ability to challenge existing conditions is blatantly limited (FAO 2012b).

Environmental impacts related to food are also problematic and cover all stages of the food chain, from food agricultural production to processing, packaging, distribution, and waste. More

specifically, the food sector, via fertilizer applications, manure, transportation, energy consumption, and deforestation, is a major contributor to direct and indirect greenhouse gas emissions. Besides the problem with energy retrieval, common environmental threats like the generation of waste, water pollution, pesticide use, and decline of biodiversity constitute other typical concerns. Moreover, the growing industrialization and intensification of agriculture has been linked to the continuing decline of biodiversity in agricultural areas. Intensive agriculture is also considered responsible for extensive drainage and extraction of groundwater, causing groundwater shortages, decline of groundwater-dependent ecosystems, and poor water quality. Similarly, the capacity of agricultural soils, crucial for a continued supply of high-quality foodstuffs, is endangered due to intensive use of the land.

As the food system approaches or crosses its natural and social boundaries, the need for effective and legitimate institutional responses becomes a challenge for both scientists and policy-makers. In this context, business and civil society institutions are often advocated as a panacea for the development of solutions to various environmental and social problems and externalities. Particularly private governance initiatives in the form of private standards and certification schemes appear to have progressed to a mainstream approach to pursuing sustainable agricultural development.

Drawing on previous research and publications by the authors, this short entry, therefore, aims to give an overview of the most prominent private institutions developed to address environmental and social sustainability challenges in the global food system and to sketch some of the most controversial debates surrounding the privatization of food governance. The transformations that led to the emergence of private food governance are discussed first.

Transformations Leading to Private Food Governance

Today, private actors, particularly transnational corporations (TNCs) and civil society organizations,

go far beyond their traditional political role as lobbyists by directly engaging in global food governance (Fuchs et al. 2011a). These private actors create institutions to “govern – that is, [...] enable and constrain – a broad range of activities in the world economy” (Büthe 2010, p. 1). State authority is either not present at all or not the predominant form of political authority in these private food governance initiatives. Two sets of transformations fostered and enabled the latter’s development: normative and structural material transformations.

Normative Transformations

In the past four decades, a shift in the objectives of agriculture and food policies from food sovereignty and a fair standard of living for the farmers to sustainable development have taken place, particularly in industrialized countries. Indeed, at the end of the Second World War, issues of food security, land reforms, increasing productivity, and technological improvement were favored on the political agenda. The aim to produce enough affordable food for the population led to state-driven policies supporting the industrialization, intensification, and rationalization of agricultural production at the national level. In a process described as the “Green Revolution,” worldwide agricultural productivity increased transforming agriculture from a relatively backward and highly labor-intensive economic sector toward one of increasing technological sophistication.

Although early agriculture and food policies were successful in their objectives, they created numerous environmental and food safety problems. Accordingly, the aims and operation of subsequent policies shifted, and sustainable development became one of the core objectives of agricultural and food policies today, i.e., they increasingly considered environmental and social consequences, in particular food safety, in addition to economic and food security concerns. Environmental, ethical, and health aspects became inalienable for policy-makers realizing that agricultural and food policies should not only concentrate on securing the income for producers and sufficient food for society. Some stakeholders and chain actors, such as consumers, farmers, and retailers, increasingly shared such

environmental, social, economic, and/or ethical concerns. As such, the quest for food sufficiency has now become a quest for food sustainability.

At the same time, the general normative environment in the political economy of Western states dominating the global agricultural system was characterized by a highly positive evaluation of market-based actors, norms, and governance strategies. The assumption that positive effects for the market translate into positive effects for society combined with a trust in the expertise, resources, and management capabilities of market actors fostered the attribution of greater governance competence to them. Government actors, in contrast, were frequently described as slow and inefficient if not corrupt, and their limited territorial jurisdiction and failure to reach international agreements used to further highlight their weakness. Encouraged by the end of the cold war, practitioners as well as scientists celebrated the idea of governance rather than government, building on presumptions of shared interests of state and non-state actors (across countries) (Rosenau and Czempiel 1992; for a critical evaluation of these governance discourses, see Fuchs (2007)). Thus, a generally favorable atmosphere for private governance existed.

Structural Material Transformations

Structural material transformations have simultaneously taken place. These changes in the agrifood sector started with the Uruguay Round (UR) (1986–1994) of the General Agreement on Tariffs and Trade (GATT), which focused on reducing barriers to trade in agricultural commodities *worldwide*. The resulting Agreement on Agriculture (1995) continues to weigh in on global agricultural politics until today, with the activities of the World Trade Organization (WTO). The resulting liberal regime to agriculture brought dramatic changes to the global food sector. The pressures for competition in the global market intensified. As a consequence, concentration of production and integration of supply chains took place, initially occurring on the supply side of food chains (Morgan et al. 2006; Josling 2002). Particularly in the USA, conglomerates such as ConAgra and Cargill became big

and powerful players in food production and manufacturing.

However, a number of developments in food retailing fostered by new food, communications, and transportation technologies led to shifts in power toward the end of the supply chain, specifically food retailers (Fuchs and Kalfagianni 2010; Henson and Reardon 2004; Nadvi 2004). First, the number of consumers increased globally, strengthening retail chains due to their strategic position between consumers and producers. Second, retailers do not depend on natural constraints which give them advantages in relation to suppliers (Morgan et al. 2006). In case of a draft in one country, for instance, retailers can source their supplies elsewhere. Third, technological changes like GPS control of transportation and deliveries by the minute helped retailers control the supply chain in a “from farm to fork” kind of manner. Last and most fundamentally, capital concentration led to the creation of big multinationals among the (food) retailers. Through global acquisitions and mergers, a diminishing number of internationally operating supermarket chains have risen to the top. Their market share increased constantly in the last two decades and led to the emergence of highly oligopolistic regional market structures (Burch and Lawrence 2005, 2007; Konefal et al. 2005; Fuchs and Kalfagianni 2010). Currently, the top 10 global retail chains control 40% of total global sales, with Wal-Mart alone being responsible for 10% (Clapp 2012).

This shift in objectives of agriculture and food policies and the rise of private actors, particularly food and retail corporations, as dominant players in the world food economy allowed and fostered the emergence of private food governance. They created both the demand for and supply of the pursuit of sustainability objectives on the basis of private – rather than public – institutions. Among these institutions, private standards are the most concrete form of private governance, as briefly discussed below.

Private Food Standards

Private standards are defined as rules of measurement established by regulation or authority (Jones

and Hill 1994). Private standards tend to be voluntary in nature and rely on various sorts of certification mechanisms to identify actors complying with the principles defined in the standard.

Most private food standards are developed by the “new food and lifestyle authorities,” which is how Dixon calls food retailers (Dixon 2007, p. 30). Via private food standards, food retailers have gained a dramatic influence on market structures and characteristics in recent years. Prominent examples of food retail standards are the British Retail Consortium Technical Standard, the Global Food Safety Initiative, and the GlobalGAP (see Fuchs et al. (2011b) for more detailed information).

Created in 1998, the British Retail Consortium Technical Standard regulates the evaluation of manufacturers of retailers’ own brand products. Certification in accordance with this standard today is required for suppliers of the majority of UK and Scandinavian retailers (www.brc.org.uk). The standard itself consists of more than 250 requirements and includes norms for food safety and quality schemes, products and process management, and the personal hygiene of personnel; for most UK and Scandinavian retailers, BRC certification is required in order to consider business with these suppliers (www.brc.org.uk). The BRC Technical Standard was followed by the BRC Packaging Standard in 2002 and the BRC Consumer Products Standard in 2003. Each of these standards is revised and updated at least every 3 years.

A group of international retailers and global manufacturers initiated the Global Food Safety Initiative in 2000 with the expressed aim of improving consumer protection and strengthening consumer confidence. The initiative currently covers 65% of worldwide food retail revenue setting requirements primarily for food safety. Furthermore, it aims to improve efficiency costs throughout the food chain.

The Global Partnership for Good Agricultural Practice (GlobalGAP, known as EurepGAP until 2007) was developed in 1997 by a group of retailers belonging to the Euro-retailers Produce Working Group (Eurep). Initially, EurepGAP focused only on fruits and vegetables. It soon

was extended to meat products and fish from aquaculture as well, however. Producers are certified on the basis of a checklist consisting of 254 questions divided into 41 “major musts,” 122 “minor musts,” as well as 91 recommendations (“shoulds”). Traceability and food safety are counted as major must practices, while minor musts and shoulds include both environmental and animal welfare concerns.

Next to retailers, processors, producers, and their associations are also engaged in governance activities in the agrifood sector, albeit to a smaller extent. Examples of producer-led governance efforts include the creation of alternative food initiatives, such as roundtables for sustainable biofuels, palm oil, sugar, and cotton, and organizations dedicated to the promotion of organic agriculture, for instance (Morgan et al. 2006).

Many of private governance initiatives developed by retailers, producers, or cooperative arrangements between the two also include the participation of civil society organizations, such as Oxfam, the World Wild Fund for Nature (WWF), or Consumers International. The degree to which these organizations participate in the governance of the standard setting organizations varies, however (Fuchs et al. 2011b). While a few organizations grant them an active role in decision making, in most initiatives they are restricted to an observational position.

Major Debates Related to Private Food Governance

Importantly, the emergence and proliferation of private food governance is not uniformly regarded as a promising new avenue in addressing sustainability challenges, particularly at the global level. In the literature, three major debates related to private food governance can be identified. They revolve around questions of legitimacy, effectiveness, and access. The following paragraphs sketch the central tenets of these debates.

Legitimacy

According to Scott (1998), legitimacy is the property of a situation or behavior that is defined by a set

of social norms as correct or appropriate. As outlined by Fritz Scharpf (1997), in modern (Western) traditions of democracy, legitimacy rests on two pillars, one based on input-oriented arguments, i.e., government by the people, and one based on output-oriented arguments, i.e., government for the people. According to input-oriented arguments, legitimacy derives from democratic procedures and formal arrangements. According to output-oriented arguments, on the other hand, legitimacy derives from the effectiveness of the specific governance institution in designing policies that promote the “public good.”

For examining the input legitimacy of private (food) governance arrangements, three criteria have been identified as important: participation, transparency, and accountability (Porter and Ronit 2010). While participation refers to the question of involvement in policy process, transparency refers to the provision of timely, reliable, and comprehensible information. It is an important dimension of legitimacy enhancing public scrutiny and visibility in complex environments, thereby also strengthening meaningful participation and ensuring accountability (Fuchs et al. 2011b). Accountability on the other hand is a crucial idea in democratic governance capturing decision-makers’ dependence on the public that ought to have the potential to “vote” them out of office (Porter and Ronit 2010).

The criticism of private food governance addresses these three criteria of democratic legitimacy. In terms of input legitimacy, critical observers draw attention to a lack of transparency and participation that characterizes many private or public-private schemes. Particularly constraints in participation provide a serious obstacle to the provision of equal opportunities to different societal actors to influence the norms and rules that govern the food system (Fuchs and Kalfagianni 2010). Discrimination in access exists especially for civil society actors and actors from developing countries but also smaller business actors and those that are further away from the consumer, e.g., small farmers. A lack of transparency also weakens the democratic legitimacy of private governance mechanisms. If private actors develop their own rules, then at least these rules should be

open to public scrutiny. This lack renders (existing) access, meaningless, due to the obscurity of the real options actors can “vote” for. In most cases, this results from the exclusion of civil society in the monitoring and implementation of standards. Finally and in almost the same manner, accountability is problematic when it comes to private food governance. With private governance institutions, accountability and mechanisms to ensure it are not predefined. To the contrary, transnational corporations are at best only accountable to a fraction of the people affected by their activities (Zürn 2004). Moreover, accountability is difficult if not impossible to enforce for efforts such as vague standards and CSR initiatives.

Despite these criticisms, the difficulty of developing measures that provide input legitimacy for private governance institutions does not escape scholars. It is a challenge to create a level playing field in participation, for instance. First, this would require a definition of who should have the right to participate. Moreover, such measures would require support for those facing resource or collective action problems hindering their participation. Similarly, it is extremely difficult to create conditions of accountability and to decide to whom private actors should be accountable in their standard setting activities and how. While transparency may seem an easy and technical, politically benign issue, the challenge of creating transparent private governance institutions should not be underestimated, either. In the past, requests for more information from business actors have often been met with arguments that such information cannot be provided due to competitiveness concerns (see Fuchs and Kalfagianni (2010) for a more detailed discussion). In short, private food governance not only suffers from input legitimacy shortcomings at the moment, but these shortcomings also seem extremely difficult to overcome.

Effectiveness

For private forms of governance, effectiveness or output legitimacy is frequently identified as a foundation for their legitimacy. After all, private actors are not elected to political office and thus not endowed with electoral authority to set rules and determine the societal allocation of values.

Instead, legitimacy claims of private governance initiatives tend to derive from the notion that they can provide certain governance functions more effectively and efficiently than elected public actors (Fuchs and Kalfagianni 2009). Thus, proponents of private governance attribute efficiency and effectiveness to their pursuit of the “public good,” in the context of global economic liberalization and increased corporate control of markets and supply chains (Bäckstrand 2006; Glasbergen 2010). In contrast, critics argue that private governance institutions are in many respects analogous to the same things they are purported to resist, and instead of fostering public goods, they extend market fetishism and undermine public national and international law (Clapp 1998; Gibson 1999; King and Lenox 2000; Quilliam et al. 2011). At best, so the critical perspective, private governance is effective only in limited circumstances and, at worst, it preempts more stringent public regulation, undermining basic core democratic values and principles.

The effectiveness of private food governance has been examined in the literature vis-à-vis its ability to address various sustainability challenges. Especially in the field of food safety, various scholars attest a positive influence of private standards (Mazzocco 1996). Moreover, they argue that standards can be a means for reaching more consumers by communicating and reassuring them regarding safety and quality (Reardon and Farina 2002). However, these apparent benefits are likely to exist only for a small subset of the original set of suppliers (Reardon and Farina 2002). Likewise, other evaluations point out the potential of private food standards to provide incentives to modernize production and allow competitive repositioning and enhanced export performance of developing countries (Jaffee and Henson 2004). The question to what extent resources for such measures exist, especially for small- and medium-sized farmers in developing countries, however, remains (Fuchs and Kalfagianni 2009).

With respect to the environmental consequences of private food governance, the jury is still out. Environmental auditing of food-related operations is currently incomplete and covers

only specific products or practices rather than the sector as a whole (Lang and Barling 2007). Nevertheless, some observations can be made. In particular, the selected nature and low priority of environmental aspects in the most prominent private food governance initiatives are noteworthy. For the GlobalGAP, for instance, which is currently present in more than 100 countries and covers 94,000 suppliers worldwide with growing membership every year, many environmental conservation practices are only recommendations. In addition, a supplier's noncompliance does not always prevent certification (Bartley 2010). The potential of GlobalGAP is further weakened by the declining emphasis on sustainability within the GlobalGAP initiative from its launch in 1997 until today (Van der Grijp 2008). In general, the question remains whether retail environmental standards are stringent and comprehensive enough to allow the reaping of significant environmental benefits (Fuchs et al. 2011b).

Finally, the effectiveness of private food governance in terms of social sustainability needs to be discussed. Private standards may include provisions regarding worker welfare, gender non-discrimination, rules against sexual harassment, and other social provisions. However, such social provisions tend to play a secondary role relative to the current understanding of food quality, as well. Some scholars argue that the presence of these standards can improve labor conditions, raise wages, and increase workers' security (Schaller 2007; Pearson 2007). However, due to their select and weak nature, social standards also suffer from a number of constraints in terms of both their scope and implementation, which severely limit their potential for effectiveness with respect to social sustainability. Fundamental challenges, such as living wages, tend to be excluded.

In short, while private food governance has been effective in addressing some sustainability challenges, specifically food safety concerns, overall its performance is highly ambiguous.

Allocation/Access

The third major debate concerns questions of the global allocation of resources and access to food. Specifically, scholars voice the concern that the

ability provided to transnational corporations (TNCs) to exercise gatekeeping control over supply chains on the basis of private standards has also fostered inequality in access to food for some groups (see Fuchs and Kalfagianni 2010). Some studies identify a potentially higher income for food suppliers, as a result of premiums to be gained or increased productivity or quality (ITC 2009). Yet critics argue that such benefits accrue only to a small subset of global suppliers, specifically those who are able to afford the costly investments and the lengthy and expensive auditing and certification processes associated with private standards (Auld et al. 2008; Klooster 2005). In contrast, small- and medium-sized farmers tend to lack the economic ability to take advantage of such opportunities (Amekawa 2009; Guthman 2007). It is estimated, for instance, that a total of over UK £2.2 million has been invested to meet the initial costs of GlobalGAP compliance in Kenya alone, representing, on average, UK £220,000 per participating company (Graffham et al. 2007). Although costs differ for small- and medium-sized companies, small-sized producers tend to depend on donors' willingness to subsidize certification (Graffham et al. 2007). In this context, the most vulnerable and financially weak actors can be pushed out of the supplier market, not being able to comply with private standards (Fuchs and Kalfagianni 2010). Thus, the constraints imposed by private standard on suppliers may affect their access to the market as much as to food, due to the existing oligopolistic market structures (Mayer and Gereffi 2010). Small suppliers in some of the most food-insecure countries have lost their livelihoods as a result of private standards (ActionAid 2005). Considering that a significant segment of the global population consists of small and subsistence farmers, this observation becomes even more dramatic. Out of the approximately 525 million farms worldwide, about 85% currently belong to smallholders or subsistence farmers who operate plots of land of less than 2 ha (Nagayets 2005). Subsistence farmers constitute over half of the world's rural poor, but they produce about four-fifths of food supplies in developing countries (<http://www.fao.org/docrep/u8480e/U8480E08.htm>, 16 June 2012).

In short, private food governance receives ambivalent evaluations, in terms of its impact on access to food, with small and subsistence farmers being particularly negatively affected.

Summary

This entry gave an overview on the most prominent private institutions developed to address environmental and social sustainability challenges in the global food system. It outlined the transformations that led to the emergence of private food governance and sketched some of the most controversial debates surrounding the privatization of food governance, particularly related to questions of legitimacy, effectiveness, and access. Regarding legitimacy, it noted scholarly concerns from the perspective of participation, transparency, and accountability. Regarding effectiveness, it underscored the ambiguous contribution of private food governance to food safety, environmental sustainability, and labor rights concerns. The discussion underlined the especially problematic relation between private food governance and access to food for some groups, specifically the most vulnerable members of the global population. In short, one core message from this entry is that while private food governance carries some promise, it by no means constitutes a panacea for addressing sustainability challenges in the global food system.

Introduction

An ecosystem is a community of living organisms, including plants, animals, and microbes, plus the nonliving components of their environment, such as water and minerals, interacting together as a system or an ecological unit (e.g., a pasture or forest). Ecosystems may also be viewed as a form of natural capital, which provides flows of vital goods and services to humans (e.g., Daily 1997). These goods and services are called ecosystem services (ES) and are often defined as the “benefits people obtain either directly or indirectly from ecosystems” (MEA 2005). Many ES are critical to human survival (e.g., climate regulation and nutrient cycling), while others contribute to our well-being (e.g., nature recreation and rural lifestyles) (Kremen 2005).

Scientists and scholars have traditionally focused on natural ecosystems, such as wetlands and ponds, for ES provision (e.g., Daily 1997). However, other scholars are beginning to recognize the crucial role agriculture plays in ensuring humans receive an adequate flow of ES to sustain our quality of life (e.g., Swinton et al. 2007). The reason is that agricultural ecosystems comprise about half of global land that is not desert, tundra,

rock, or boreal, which makes farmers the chief managers of the most productive lands on Earth (Tillman et al. 2002). How farmers manage this land greatly impacts human health and well-being, the land's future productivity, neighboring ecosystems such as wetlands and forest, and the sustainability of the world's food supply (Foley et al. 2005; Horrigan et al. 2002). Despite this importance, most farmers face strong incentives to manage their land for the short-term production of food, fiber, or fuel. The long-term health of agricultural ecosystems, however, as well as their ability to sustain food production and to provide society with diverse benefits, requires that farmers expand their management focus to include the provision of ecosystem services (ES) (Goldman et al. 2007; MEA 2005). In fact, some scholars argue that one of the greatest needs in agriculture, if not the greatest, is the provision of nonproduction-related ES such as water purification and climate regulation (e.g., Antle and Capalbo 2002).

Thus, one of the most fundamental ethical issues surrounding the provision of ES is how to encourage farmers to promote, develop, and manage ES – that is, how to encourage them to overlook short-term incentives to focus primarily on production-related agricultural services and adopt a longer-term public interest perspective by considering the provision of ES. Some relevant questions include: What ES ought to be provided? Do people have a right to specific ES, such as water cycling, clean air, or climate control? If so, whose duty is it to provide ES? If it is the farmers' duty to provide agriculture-related ES, should farmers be paid for provision? If so, how much should they be paid, how should their provision be monitored, and how will we know when society has enough ES? If farmers are not paid for provision, what other incentives must be created to ensure enough ES are provided to sustain our quality of life? (For a discussion, see Swinton et al. 2007; Kroeger and Casey 2007; Power 2010).

The importance of understanding incentives in the provision of ES can be illustrated in two ways. First, some traditional agricultural products and ES, such as corn and pest control, can be complementary products, creating a win-win situation for

agricultural producers. For example, setting aside a small area of land as habitat for crop pollinators provides a vital ES, which in turn might increase the value of crop production by more than the opportunity cost of the income forgone from not planting the habitat area in crops (Wossink and Swinton 2007). Conversely, many traditional agricultural products and ES are competitive products, creating a win-lose scenario in which the farmer has little incentive to provide the ES (Wossink and Swinton 2007). These competitive ES include flood control, carbon sequestration, and water purification – vital ES that our society highly values, yet which are underprovided (Lant et al. 2008).

Second, agricultural activities that result in harm to the environment, such as intensive livestock or crop production that results in animal wastes or chemical fertilizers seeping into aquatic ecosystems, could become positive ES with the right incentives. Often what is needed is a change in just a few management practices. For example, the siltation of streams resulting from tillage agriculture can become an ES of soil retention with the adoption of conservation or no-tillage practices, grassed waterways, or permanent vegetative buffer zones beside streams and lakes.

Accordingly, this entry articulates the ethical issues of providing ES in agriculture, with a particular focus on the incentives farmers face to do so. Specifically, the objectives of this entry are to discuss ecosystem services and the critical role agriculture may play in ES provision and to discuss the three types of solutions currently being considered to help solve the underprovision of agriculture-related ES.

Ecosystem Services in Agriculture

Although the provision of ES in agriculture sounds complex, it can be viewed simply as the efforts of agricultural producers to enhance the viability and stability of agricultural ecosystems by choosing management practices that jointly produce nonproduction-related ES alongside livestock and crops.

Provision of Agricultural Ecosystem Services, Table 1 Selected ecosystem services (ES) and ecosystem disservices (ED) from agriculture

ES type	ES from agriculture	ES used as inputs	ED from agriculture
Regulating services	Soil retention	Soil retention	Soil erosion
	Pollination	Pollination	Competition for pollination
	Pest control	Pest control	Pest outbreaks
	Water purification		Nutrient runoff
			Pesticide runoff
	Habitat provision		Habitat loss
	Atmospheric regulation		Greenhouse gas emissions
	Flood control		Flooding
Supporting services	Seed dispersal		Loss of seed dispersal
	Soil structure	Soil structure	Soil compaction
	Soil fertility	Soil fertility	Soil fertility loss
	Biodiversity	Genetic biodiversity	Biodiversity loss
	Water cycling	Soil moisture	Soil moisture loss
			Competition for water from other ecosystems
Cultural services	Nutrient cycling	Soil nutrients	Eutrophication of rivers, estuaries, and lakes
	Aesthetic landscape		Loss of aesthetic value
	Recreation		Loss of recreation value
	Spiritual well-being		Loss of well-being
	Rural lifestyles		Loss of rural culture and lifestyles
Production services	Food		
	Fuel		
	Fiber		

Source: Reproduced from Stallman (2011)

Dale and Polasky (2007) identified three critical ways in which agriculture interacts with ES. First, agricultural ecosystems provide many vital ES. As shown in Table 1, these include production services such as food, fiber, and fuel; regulating services such as soil retention, carbon sequestration, and pest control; supportive services such as nutrient cycling, soil fertility, and water filtration; and cultural services such as spiritual well-being, nature recreation, and rural lifestyles. Although agricultural ecosystems have traditionally been managed to primarily provide production services, they may also be managed to provide other ES jointly with food, fuels, and fiber (Wossink and Swinton 2007; Dale and Polasky 2007). In fact, the type, quality, and quantity of ES that agriculture can provide are directly affected by the management decisions of the farmers, both individually and collectively (Dale and Polasky 2007).

Second, agriculture requires many ES as inputs to production, especially soil fertility, pollination, genetic biodiversity, nutrient cycling, and pest control (Zhang et al. 2007; Power 2010). Some of these ES are provided by the agricultural ecosystem itself, while others are provided by nearby natural ecosystems that exist within the greater agricultural landscape, such as woodlots, wetlands, and ponds (Zhang et al. 2007). Whether any particular agricultural ecosystem provides these input-related ES depends on the management decisions of farmers, including the farmer who uses the ES for production and the neighboring farmers (Goldman et al. 2007; Dale and Polasky 2007; Power 2010).

Third, agriculture affects the quality and quantity of ES which other ecosystems, such as forests or estuaries, can provide (Dale and Polasky 2007). If the effects on other ecosystems are negative, they are called “disservices” of agriculture and

often lay on the opposite end of a continuum from some important ES. For example, if a farmer practices conservation tillage, the farmer's land may provide the vital ES of soil retention. If a farmer uses conventional tillage practices on sloped fields, however, the land may provide the opposing disservice of soil erosion, plus the resulting environmental degradation caused by stream sedimentation, loss of soil fertility, and the chemical contamination of water. These disservices in turn affect the quantity and quality of ES that the stream or downstream lakes and estuaries can provide (Dale and Polasky 2007; Zhang et al. 2007). For example, a lake that is contaminated with phosphorus, nitrogen, pesticides, and sediments provides fewer ES and lower-quality ES, such as wildlife habitat, biodiversity, and nature recreation, than a lake that has not been contaminated (Zhang et al. 2007).

As a result of these three ways in which agriculture interacts with ES – the ability to provide ES, the requirement of ES as inputs, and the ability to affect neighboring ecosystems' provision of ES – managing agricultural lands to provide more and higher-quality ES has the potential to greatly increase the sustainability of agricultural ecosystems, to increase the sustainability of neighboring ecosystems, and to decrease the environmental damage which may accompany intensive agriculture (Horrihan et al. 2002; Tillman et al. 2002; Foley et al. 2005; MEA 2005). Most scholars agree, however, that increasing the provision of ES in agricultural ecosystems will not be easy (e.g., Goldman et al. 2007) and will likely require society to change the incentive structure that farmers currently face (e.g., Swinton et al. 2007).

Incentive Structures in Agricultural Ecosystems

Although joint production of traditional agricultural products, such as corn, and nonproduction-related ES, such as wildlife habitat, is both possible and desirable (Wossink and Swinton 2007; Robertson and Swinton 2005), most farmers face strong incentives to manage their land for the short-term production of food, fiber, or fuel,

often at the expense of other vital ES (Tillman et al. 2002; Swinton et al. 2007). For example, most farmers manage their land for the provision of production-related ES, such as wheat, because these services are private goods; the farmer enjoys most of the benefits of production (e.g., income from the crop) but does not pay all of the costs (e.g., loss of income in a downstream community due to eutrophication of fisheries from excess nitrogen in the water). Likewise, farmers disfavor the provision of cultural, supportive, or regulating ES, such as water purification, because the farmers pay all (or most) of the costs of provision (e.g., leaving land out of production next to a stream) but only enjoy a portion of the benefits (e.g., better bird watching on the farm). In some cases, farmers pay all of the costs of provision but receive no benefits, either because their efforts have no discernible effect on the ES (e.g., one farmer's effort to improve water quality in a large lake) or because the ES is appropriated by other users (e.g., flood control for downstream communities).

Incentive structures where the provider pays all or most of the provision costs but only receives a portion of the benefits are associated with public or quasi-public goods, which are how most scholars classify ES (e.g., Swinton et al. 2007). This incentive structure leads to an underprovision of ES because of the free-rider problem; people have little incentive to pay the cost of providing a public good when someone else might pay the cost of provision, and the non-payer or free rider can still enjoy all of the benefits of the good (Olson 1965).

Solutions to the free-rider problem usually involve government provision or a restructuring of incentives to encourage private provision. How to best restructure these incentives, however, is an ethical problem that scientists, scholars, and other stakeholders have yet to solve. Many scholars believe the traditional government and market solutions for the provision of public goods will provide the most effective way to increase ES provision in agriculture (e.g., Kroeger and Casey 2007). A growing number of scholars, however, recognize the potential of a third major approach – cooperative solutions where landowners work together to provide ES (e.g., Sarker et al. 2008).

In fact, some agriculture-related ES are particularly well suited to cooperative provision (Stallman 2011). The following sections describe these three major approaches to ES provision.

Market and Government Solutions

In the case of agricultural-based ES, government and market solutions are designed to reduce the free-rider problem by changing the incentive structure that farmers face. This may mean (1) increasing the cost of not providing an ES (e.g., assessing a fine if a farmer fails to create a buffer zone along a stream corridor) or (2) increasing the benefit of ES provision (e.g., creating a mechanism for farmers to receive price premiums on products that are produced in conjunction with ES). These solutions to ES provision may include legal approaches, such as liability laws and property rights; policy approaches, such as taxes and subsidies; educational approaches, such as extension services and public education classes; induced market approaches, such as cap and trade and regulation-driven markets; and free-market approaches, such as eco-labeling, food tracing systems, and marketing cooperatives dedicated to sustainable agriculture (Kroeger and Casey 2007; Bräuer et al. 2006; Swinton et al. 2007).

Although these government and market solutions have the potential to increase ES provision in agriculture, many controversies and barriers to their implementation exist. For example, many government and market solutions may be costly to implement, monitor, or run (e.g., Power 2010; Kroeger and Casey 2007). Measuring and monitoring of ES may be especially problematic because many ES are so interrelated that it is hard to distinguish one from the other or to define them, so double counting becomes a risk (Dale and Polasky 2007; Swinton et al. 2007). Plus, we do not currently have the technical ability to measure some ES accurately enough to monitor provision (Swinton et al. 2007). Other barriers to market and government solutions include (1) the cost of creating and running new markets, such as a carbon exchange market; (2) the cost of creating and running a certification systems, such certified

organic products; (3) the costs of regulating the opposing disservice if ES are not provided, such as regulating nonpoint source pollution in streams; (4) start-up costs for farmers, such as the equipment, education, and input costs associated with switching from conventional tillage to a no-tillage system; (5) information costs, such as technical knowledge of the management practices that will provide ES or the knowledge of why ES may be important to agricultural sustainability; (6) lack of trust in the governmental agency responsible for the payment of ES program, such as a state conservation agency (e.g., Raedeke et al. 2001); and (7) social and psychological costs, such as fear of the unknown or the social risk of being different (Carolan 2005; Koundouri et al. 2006).

Consider a farmer who wants to practice integrated pest management (IPM) as part of a program to improve water quality in a stream used for municipal drinking water in a downstream rural community. To effectively practice IPM, the farmer must know how to monitor soil, crops, and pest populations in order to target the timing, placement, and amount of fertilizer or pesticide needed to achieve the greatest benefit for the crop without using excess chemicals (Flint and Van den Bosch 1981). This skill set requires knowledge and experience that many farmers and extension personnel lack or cannot find access to, despite increasing demand for the knowledge (e.g., Carolan 2006; Rodriguez et al. 2009; Hayes 2001). In fact, Carolan (2005) found that almost three-quarters of extension personnel and agricultural professionals in Iowa lacked the technical knowledge to assist a farmer in implementing sustainable agricultural practices such as IPM. In addition, many sustainable farming practices such as IPM are proven effective when used together as a management system, but may not be cost- or time-efficient when used alone (Carolan 2006). For example, farmers practicing basic IPM techniques, such as monitoring crops for pests, may also benefit from knowing how to enhance pest control through cultivation techniques, crop rotations, disease- or pest-resistant cultivars, the use of cover crops, or a complete redesign of the farmers' operation to enhance the ecological processes that would make use of pesticides or

herbicides unnecessary. Again, information costs for these complementary practices are high, as are the start-up costs for the farmer, especially those who are redesigning their operation, not just making minor changes to conventional practices (Macrae et al. 1993). Farmers who practice IPM may also face social costs in the form of criticism or trust issues with neighbors or landowners who hold traditional beliefs that “weedy” fields and “unkept” hedgerows reflect poorly on the farmer’s character (Carolan 2005, 2006). Finally, the full benefits of IPM may be hard to monitor. For example, IPM not only may provide the ES, such as water quality, but may also provide or enhance other vital ES, such as soil fertility, soil structure, soil retention, nature recreation, water cycling, natural pest control, and pollination services, some of which are so interrelated that it would be hard to monitor them separately (Barrios 2007; Dale and Polasky 2007; Swinton et al. 2007). How the farmer or a government agency responsible for payments for ES will recognize and monitor these changes is uncertain.

Although farmers and government officials face many implementation barriers to government and market solutions, many scholars believe these solutions may help encourage the provision of agriculture-related ES (e.g., Kroeger and Casey 2007). Some scholars, however, question if these traditional approaches to the free-rider problem are enough (e.g., Goldman et al. 2007). The goal of most government and market solutions is to entice enough farmers to manage their land for the provision of nonproduction-related ES so that a socially desired quantity of ES is achieved. One potential problem with these approaches, however, is that they often ignore the fact that many ES require landscape-level management to provide optimal benefits (Goldman et al. 2007). In other words, individual incentive approaches ignore the potentially large and important incentive of a collective benefit which only may be achieved if most of the farmers in the region cooperate in their effort to provide ES (e.g., Sarker et al. 2008). It is in this context that cooperative solutions become important.

Proponents of cooperative approaches often point to the spatial scale mismatch between ES

and agriculture as justification for its necessity (e.g., Goldman et al. 2007). This mismatch occurs because the spatial scale of management in agricultural ecosystems (e.g., a 500 acre farm) often does not match the spatial scale of ecosystem processes necessary to provide ES (e.g., a tri-county watershed), making cooperation necessary (Cumming et al. 2006; Pelosi et al. 2010).

The Collective Benefit of Collective Management

Ostrom (1990) argues that collective management is a viable, yet commonly overlooked, third solution to the underprovision of a natural resource such as ES. Collective management often involves a group of citizens who jointly manage a community-owned property, such as a group of herdsman who manage a common pasture. It may also involve a group of citizens who jointly manage individually owned properties such as members of a neighborhood association who jointly make and follow rules regarding noise levels in order to better enjoy their neighborhood.

When people work together, they often achieve a collective benefit that could not be achieved by the group members’ individual efforts. In the collective management of a natural resource, most participants hope to achieve the collective benefit of a stable resource base, although other collective benefits may be achieved. For example, an inshore fishery in Alanya, Turkey, was threatened by hostilities, harvest uncertainty, and lost productivity because fishers were fighting over the most productive fishing spots (Berkes 1986). In response, members of the local fishing cooperative devised a set of rules which assigned fishing spots on a daily basis, giving each fisher an equal chance to fish highly productive spots and less productive spots. This collective management regime, enforced by the fishers themselves, created a more productive fishery since better spacing of the fishers optimized production at each site. In addition, fishers no longer wasted resources searching for or fighting over sites, plus they achieved more harmonious relationships within their community. Each of these benefits represents a collective benefit that could not

have been achieved by the fisher's individual efforts. These collective benefits were only achieved because the fishers worked together to devise and enforce a set of rules for managing the local fishery (Ostrom 1990).

In the collective management of an ES, participants may hope to achieve the collective benefit of enhanced ES provision, environmental damage mitigation, or the prevention of future regulations (e.g., Lubell 2004). For example, Ayer (1997) describes cotton farmers in Arizona who collectively managed for pest control by practicing collective integrated pest management (IPM) – a management system that requires monitoring pest populations and only applying pesticides when a certain threshold is reached. After devising and enforcing a set of collective IPM rules, these farmers achieved fewer pest outbreaks, drastically reduced input costs, and reduced confrontations with neighboring communities regarding water and air quality issues – benefits that were only achieved when most of the cotton farmers in a region worked together to enhance the ES of pest control (Ayer 1997).

Although some ES, such as pest control, are well suited to collective provision (Stallman 2011), collective solutions also face many barriers to implementation (e.g., Ostrom 1990, 2001). In addition to many of the same barriers that farmers face with government and market solutions – such as start-up costs, information costs, lack of trust in the sponsoring agency, and social costs – farmers who work together to provide ES also face barriers such as lack of trust in other farmers or stakeholders, lack of information about other farmers' past actions, lack of a common vision, or organizing costs, especially with large groups (Olson 1965; Ostrom 1990, 2001, 2009; Pretty 2003).

Consider the previous example of an individual farmer who wanted to begin practicing IPM after joining a government program to help provide higher water quality to downstream rural water municipalities. Now consider twenty farmers who must work together to accomplish the same goal. Water quality is highly dependent on landscape-level processes (e.g., Sarker et al. 2008) and is well suited to provision through collective management (Stallman 2011). In fact,

encouraging farmers and other stakeholders to work together may be the only way water quality may be significantly improved. However, farmers working together must agree on a common vision for their work. They must come up with a set of rules and guidelines to follow, and they must trust that other farmers in the group will follow through on their commitments (Ostrom 1990, 2001). Additionally, the farmers face the same start-up costs, information costs, etc. that each would face individually if they wished to provide ES.

Summary

Because agriculture has such an enormous effect on the environment, farmers are in a unique position to provide ecosystem services. They can do this through the farm, ranch, and agricultural management practices they adopt. However, farmers face short-term incentives to focus on production-related services, often at the expense of providing longer-term benefits of ES. For this reason, the underprovision of ES can be defined, as Lant et al. (2008) did, as the “Tragedy of Ecosystem Services,” in honor of Hardin's (1968) analysis of the “Tragedy of the Commons.” The tragedy results from the overconsumption of common pool resources, such as pasture lands, and from the underprovision of public goods, such as carbon sequestration. Thus, one of the most important ethical issues that surrounds the provision of ES in agriculture is similar to the problem of providing any public good or managing any common pool resource – which is how to identify and encourage the provision of ES by those most capable of doing so.

Since the ethics of providing ES revolve around the problem of incentives, this entry described the role agriculture plays in providing ES and the types of solutions currently considered and adopted to help solve the underprovision of ES.

Introduction

The term “institutional foodservice,” which is increasingly a topic of interest among policymakers and advocates, hinges on a convenient but slightly misleading term: institution. At first consideration, institutional foodservice may be thought of as only including food served through large institutions like schools, jails, hospitals, and employers. However, the term is also increasingly being used to refer to food paid for by public dollars (New York City Council 2010; Public Plate Working Group 2014), sometimes called “the public plate” (Morgan 2006). This definition extends institutional foodservice beyond these often large bricks-and-mortar institutions to potentially include soup kitchens, home-delivered meals for seniors, and snacks given out in public child-care settings, among other types of food. At the same time, because of the public nature of the funding, this latter definition may exclude many private employers, colleges, universities, and hospitals, which are some of the institutions that have been at the forefront of institutional food systems change (Barlett 2011; Eldridge 2012).

Institutional food has been a part of city life for decades if not centuries, but in recent years, it has attracted renewed attention from policymakers and advocates as a possible and important site of food systems change. In this entry, several key features of contemporary institutional food in the United States will be briefly discussed. While many of these concepts may apply both to public

and private organizations providing food, there is an emphasis in this entry on the concepts most relevant to the public provision of food. New York City, which currently provides more than 270 million meals and snacks per year (City of New York Mayors Office of Contract Services 2012), operates a complex and increasingly innovative institutional food system, which is the source of many of the examples provided in this entry.

Key Features of Contemporary Institutional Foodservice

Institutional food, especially in the public sphere, is typically the product of several forces that are often challenging for institutional food managers to balance and reconcile. These forces include (1) the usually limited and sometimes complex financing of institutional food, (2) consumer preferences, and (3) compliance with institutional food quality standards (Public Plate Working Group 2014). Several other factors relevant to these forces and critical to understanding institutional food are (1) the structure of purchasing, (2) the location of preparation, (3) institutional food labor, and (4) trends in institutional food systems change like attention to the health impact of institutional food, attention to sustainability, and attention to local economic development. Each of these topics will be discussed in turn.

Financing

Financing of food varies from institution to institution, though public agencies or publicly funded organizations often find themselves having to provide institutional food on extremely limited budgets. In the case of a senior center being contracted by a city agency, for instance, the senior center may bid to provide all of the services that senior centers provide, including foodservice. Food would be part of the bid, and while there may be specific characteristics of the food that the city can specify (e.g., being served a certain number of times per day or meeting certain nutritional requirements), the senior center is likely to try to

bid the lowest amount possible for the provision of this food in order to help keep their overall bid low, so that they remain a viable candidate in procurement systems that typically must prioritize the lowest bidder in contract decisions. When a city provides food directly – for instance, through a city-run homeless shelter – a similar logic may be in play through a slightly more streamlined purchasing route. In this situation, the city might contract food providers directly but would likely still be seeking the lowest bid for the type of food needed.

In the cases of some of the largest institutional food systems in the United States, like the primarily federally funded school food system that operates in public and some nonprofit private elementary, middle, and high schools, the challenge of providing food has to do not only with limited budgets but also with addressing consumer preferences that help to determine financing. There are three eligibility levels that organize the funding of food in American public schools. Based on their family income level, students may qualify for free meals, reduced-price meals, or full-price meals, though even full-price meals are subsidized by government funding. The reason that these categories are important is that schools receive different levels of reimbursement for meals served at each of these levels. However, this is not the only factor that determines the reimbursement rate. The amount of money a school receives for each meal served is also determined by the percentage of lunches served at the free or reduced-price rate for the school overall (a proxy for the school's overall level of need) and by whether or not new federal nutrition standards that went into effect in 2012 have been successfully implemented. Students paying for full-price meals are also important to school food budgets. The financing of school food thus works best at schools that can attract the largest percentage of students at all levels of reimbursement to eat school lunch. This dynamic is amplified by the fact that schools receive a small amount of funding for each lunch served that can be used toward foods provided directly by the US Department of Agriculture (USDA). These supplemental foods are colloquially known as “commodity

foods” (Public Plate Working Group 2014). The importance of consumer preferences will be discussed further in the next section.

Consumer Preferences

While consumer preferences are a primary guide for those designing restaurant menus, they may not seem as important in institutions serving food with public dollars to those in need. Though some institutional food settings give consumers choices among foods that are offered and must make institutional eating appealing to keep reimbursement totals high (as in the American school food system), others may offer a single primary meal to all consumers each time a meal is served with relatively little attention to consumer preferences. Historically, this lack of attention has led to institutions like schools and prisons becoming notorious for serving unappealing foods. Food may even be used as a kind of disciplinary tool in correctional settings, a practice that raises ethical questions and that has generated lawsuits in several states. The classic American example of this is the *nutruloaf*, which continues to be used in many states despite numerous lawsuits. This is typically a starchy product made of a variety of ingredients that have been processed, mixed, and baked into a loaf, which offers basic nutrition in a form that is poor tasting, constipating, and served without utensils (Greenwood 2010).

In spite of these examples to the contrary, however, making sure that consumers can eat the foods that are provided is typically important to institutions both from the perspective of making sure that the basic health and well-being of consumers is maintained through eating and from the perspective of limiting food waste. Many types of institutions offer kosher and halal meals to those who require these for religious reasons, as well as therapeutic diets (low sodium, low carbohydrate, modified protein, modified consistency, etc.) to those who need or have been prescribed them by a physician for health reasons. In stark contrast to the disciplinary use of the *nutruloaf*, some correctional institutions are attentive to food preferences of inmates. For instance, the New York City Department of Correction has worked to develop vegan meal options as they have noted an

increasing preference for this among some inmates (Public Plate Working Group 2014).

As discussed briefly above, schools are an arena in which the choice by consumers to eat institutional food has the potential to dramatically affect the funding of institutional food. Because of this, over the last few decades, schools have worked to provide foods that are appealing to students, which has resulted in school food that often looks as much like commercial fast food as possible (Poppendieck 2010), creating ethical tensions for many school food directors. More recently, however, both government and civil society efforts have sought to improve the quality of school food in terms of nutrition, freshness, and taste, and there are small signs that student preferences in some areas may be starting to shift toward healthier fare as well. As an example, in 2013 in New York City, a public elementary school adopted an all-vegetarian menu due to student demand, seemingly one of the first schools in the United States to do so (New York City Department of Education 2013).

Compliance with Institutional Food Quality Standards

When receiving services or participating in some institutional settings, it may be difficult for people – especially those of limited financial means – to access other forms of food. Additionally, many people eating regularly in public institutions are considered vulnerable populations when it comes to health (for instance, populations who are poor, sick, young, and old). For these reasons, government agencies and institutions in the United States and other countries often pay special attention to certain aspects of the quality of institutional food.

First among these compliance priorities is usually basic food safety. Most places serving food in the United States, including but not limited to institutional settings, are required to develop and adhere to systems based on Hazard Analysis and Critical Control Points (HACCP) principles, which comprise “a systematic approach to the identification, evaluation, and control of food safety hazards” that is internationally used and recognized (National Advisory Committee on

Microbiological Criteria for Foods 1997). In institutional foodservice settings, as in other foodservice settings, implementing these principles typically involves hazard analysis and control throughout the receiving, storage, cooking, cooling, warming, portioning, and serving phases of meal production (Federal Institute for Risk Assessment 2013). In institutional settings, compliance with these is often ensured via monitoring by local health departments and by the requirement that someone on staff holds a certificate demonstrating training in safe food handling.

In the United States, basic nutritional soundness is also encouraged in many institutional settings and is monitored primarily by government programs that fund institutional food. Often attention to nutrition standards is incentivized by linking compliance with reimbursement. One example of this type of nutrition-oriented reimbursement is the Child and Adult Care Food Program (CACFP), which is funded through the Food and Nutrition Service of the USDA. CACFP reimburses for meals provided to children, youth, and adults through public and nonprofit child-care centers, afterschool programs, and adult day-care programs and for meals provided to children and youth residing in emergency shelters (Child and Adult Care Food Program 2013). Institutions seeking reimbursement from CACFP for meals must comply with meal patterns that are determined separately for infants of different ages, children of different ages, and adults. Breakfast for a child between the ages of 3 and 5, for instance, must include the following three components: (1) three-quarters of a cup of milk, (2) half a cup of fruits or vegetables, and (3) a serving of a grain product made from whole-grain or enriched meal or flour (Child and Adult Care Food Program n.d.).

In addition to these nutritional standards tied to reimbursement, some cities like New York have begun experimenting with improving the nutritional quality of publicly funded food even further. The New York City Food Standards created nutrition standards for all meals and snacks that city government institutions serve or purchase (New York City Department of Health and Mental Hygiene n.d.). These standards were first

instituted in 2008 and include standards for purchased food, standards for meals and snacks, nutrition standards for certain foods served, population-specific standards and exceptions (for groups with possible special needs like young children and seniors), and sustainability recommendations to support foods served to better comply with overall health and environmental sustainability. Some of the major changes resulting from the implementation of these standards – many of which were later adopted nationally for school food – are requiring whole wheat bread instead of white, two servings of fruits and vegetables for each lunch or dinner served, and low-fat or skim milk in lieu of whole milk (except for children under two). The standards are monitored in some cases by nutritionists employed by city agencies through site visits and interviews and in other cases by the contracted organizations serving food through self-report.

Structure of Purchasing

The purchasing of food is a key concept in the institutional arena because it influences both the types of foods that are available to be prepared and eaten and the affordability of those foods. Government agencies may directly contract for food or distribute funds to contractors to purchase their own food. Direct purchasing may allow agencies to better monitor the quality of food, to better negotiate low prices because they tend to purchase larger quantities of food, and to ask vendors to develop particular products made to particular specifications. For example, in the case of the New York City Department of Correction, which purchases food centrally, these factors have allowed the agency to work closely with vendors, experimenting with different product formulations until they reach one that complies with nutritional goals, is easy to cook, and has the desired color, texture, and flavor (Public Plate Working Group 2014).

In other institutional arenas, however, each site might do its own purchasing. For instance, in New York City, child-care centers overseen by the city do not purchase foods centrally. Instead, subsidized child-care providers are selected and contracted by the city and then are responsible

themselves for providing food to children who enroll (Public Plate Working Group 2014). In these situations, purchasing of food by individual sites may discourage lower bulk pricing and typically does not allow for the development of specific products. However, these smaller-scale purchasing systems may allow sites greater ability to tailor menus to their particular consumers, greater flexibility to change vendors for particular products or prices, and the ability to develop their own relationships with vendors.

Recognizing that economies of scale can be useful to institutional settings that do purchasing in this less centralized way, umbrella organizations and associations of institutions often seek out group purchasing options. New York City, for instance, now enables and encourages child-care organizations and other institutional sites that contract for food to purchase a wide array of goods and services together through a company providing this service (Public Plate Working Group 2014).

Location of Food Production/Preparation

Institutional food may be prepared primarily at the site where services are provided, primarily at a central kitchen serving multiple sites, primarily by food manufacturing companies, or primarily by a catering company that delivers chilled or frozen meals. The option that is used depends on a number of factors, including many of those discussed in this entry. Institutional food financing and scale, for example, may determine whether there is funding for staff, training, and equipment to prepare food on site. The need to monitor certain aspects of institutional food quality may also influence where food preparation takes place. For large public school systems, for instance, which must meet nutritional standards on strict budgets, and which can be liable if food safety issues arise, it may be easier to meet standards for nutrition and hygiene when foods are produced using more centralized and standardized processes as in a central kitchen or via food manufacturing companies.

Institutional Food Labor

Relatively little is known about who institutional food workers are, how they have been trained, and

how they do the daily work of making food for at-risk groups, though they may strongly influence the types and quality of institutional food (Tsui et al. 2013). The members of the institutional food workforce who have received the most attention thus far are school food workers who come into view occasionally via portrayals on television shows, analyses of school food worker contracting (McCain 2009), and, more recently, news of their union protests in Chicago (Eng 2012). However, throughout most of the literature that deals with institutional food, the figure of the worker is almost invisible. This is particularly the case in institutional settings that tend to be less centrally controlled than school food and more community-based, like child-care and senior-care settings. What can be said about institutional food workers is that they are part of the larger sector of foodservice workers who are typically low paid and receive few benefits (Tsui et al. 2013) (Restaurant Opportunities Centers United 2011).

Trends in Institutional Food Systems Change: Health

As this entry suggests, basic food safety and healthfulness have been important goals in many but not all types of institutional food settings for decades. More recently, however, a trend toward actively using institutional food as a lever for improving public health has emerged. This trend toward “Healthier Food in Public Places,” as the Center for Science in the Public Interest calls it, has been embraced by numerous cities and government agencies. The rationale for adopting policies and practices to improve the healthfulness of institutional food (and other forms of publicly funded food) that is commonly articulated by these groups includes that these efforts can potentially (1) serve as a low-cost strategy to reduce obesity and diet-related disease, (2) influence social norms around food, and (3) alter how food manufacturers operate and the nutritional value of what they produce (National Center for Chronic Disease Prevention and Health Promotion 2010). With these ideas in mind, cities often begin, as Philadelphia and Chicago did, by working to change nutrition standards in vending machines

in particular settings like city buildings, schools, and recreation centers (Philadelphia Department of Public Health 2010; Press Office 2012). Cities often then tackle applying nutrition guidelines to food served in meetings at city agencies and then may expand to developing nutrition standards for all food that is purchased or served to consumers by city agencies, as has happened in New York (Center for Science in the Public Interest n.d.).

It is also worth noting that the mission of many institutional food programs includes working to ameliorate **food insecurity**, which also threatens health. Addressing food insecurity through institutional food provision can be done in a targeted way, as in soup kitchens and homeless shelters that provide meals, or via a broader approach where larger meal programs are developed in part to help reach food-insecure populations. Universal school meal programs that feed both students who are food insecure and those who are not seek to address food insecurity in this way.

Trends in Institutional Food Systems Change: Sustainability

Health is not the only rationale in play, however, when it comes to changing institutional food. Institutional food has the potential to influence environmental sustainability through the distance food travels, the types of transportation and routes that are used to deliver food, and the waste created in the production and serving of food, among other factors. Efforts to increase the sustainability of institutional food often come packaged with initiatives to improve health, as in the American Centers for Disease Control's "Health and Sustainability Guidelines for Federal Concessions and Vending Operations" (National Center for Chronic Disease Prevention and Health Promotion 2010). These guidelines apply to many foodservice concessions and vending machines managed by the federal government in the United States. In addition to nutrition and food selection guidelines, this document recommends a variety of sustainability measures including participation in recycling and composting programs, promotion of reusable beverage containers and tap water consumption, use of green cleaning practices and pest control, and use of compostable

materials when disposable serving items (like trays) are used. Guidelines pertaining to the seasonality, local procurement, and organic labeling of food are also discussed.

Sustainability efforts in institutional food also may emerge separately from health improvement efforts. For instance, Rikers Island in New York City, which is home to the majority of inmates in the city's jail system, hosts a composting site that was originally put in place in 1996 as a way to help manage large quantities of organic waste concentrated on the small island (New York City Department of Sanitation n.d.-a). Institutional composting pilot programs in public schools and through other city agencies have also been launched in New York (New York City Department of Sanitation n.d.-b).

Trends in Institutional Food Systems Change: Local Economic Development

Lastly, economic development also frequently serves as a rationale for changing institutional food systems, especially when shifting toward more **local** (defined in a variety of ways) and regional purchasing and processing of food is a focus. This was very much the case in a 2010 report entitled "FoodWorks: A Vision to Improve NYC's Food System" published by the New York City Council. This report sought to "identify ways to move from an unsustainable food system to one that promotes health, environmental sustainability, and a thriving economy" (New York City Council 2010). While this report was not focused only on institutional food, it strongly highlighted the purchasing power of New York City's government and public institutions and the effects this could have on regional and local economies. Similarly, in Michigan, economic development has been used as a tool for framing the need for institutional food systems change. As the state's Good Food Working Group wrote in 2010, "We envision new approaches to food purchasing in which these Michigan institutions provide local, good food to consumers and create new markets for products grown, raised and processed in Michigan" (Michigan Good Food Work Group 2010). Initial steps that can be taken to increase local purchasing of foods include policy changes like

Local Law 50 of 2011 in New York City, which allows a measure of preference for local foods in institutional purchasing (Mayor's Office of Contract Services 2012). Many jurisdictions and approximately 10,000 schools across the United States are also experimenting with farm-to-school programs, which help to redirect funds spent on school food to local farms (National Farm to School Network n.d.). Other farm-to-institution programs establish similar programs for hospitals, colleges, and child-care settings (Berkencamp and Mader 2012; Health Care Without Harm n.d.; Community Food Security Coalition n.d.).

Summary

This entry discusses the institutional foodservice sector, focusing primarily on publicly funded food in cities. Dynamics that must be balanced by public institutional food systems are examined, including the financing of institutional food, consumer food preferences, and compliance with institutional food quality standards. Several other factors relevant to these dynamics and critical to understanding institutional food are also introduced including (1) the structure of purchasing, (2) the location of food preparation, (3) institutional food labor, and (4) trends in institutional food systems change like attention to the health impact of institutional food, attention to sustainability, and attention to local economic development.

Punishment and Food

Jennifer Hostetter

Food Culture and Communications, Winter Park,
FL, USA

Synonyms

Food and discipline; Food as a weapon; Food deprivation; Forced feeding

Introduction

Because food is fundamental for the preservation of life, it is a powerful and effective tool for the execution of punishment. This biological aspect, in itself, is reason enough to explain why food is such a compelling weapon. Yet the human relation to food extends beyond the physical. Individual food habits are profoundly influenced by culture. The act of eating – what, why, how, when, and with whom one eats – is defined by a complex set of social values and rituals that signify one's membership within a specific group and give one's life meaning. The extent to which a person abides by these norms symbolizes who that person is. In this sense, eating is closely linked to an individual's sense of personal and social identity. Food punishments, whether by deprivation or forced feeding, can threaten one's physical well-being as well as one's sense of self when used for harm. When food is used to discipline the body as a means of moral correction – even if it is meant for good – it goes against the human will and thus feels very much like punishment. Whatever the context, punishing with food is a means of exercising control over others or over one's own body.

The sections below will cover the major areas where food punishments occur: in the family, in prisons, in the political sphere, and in the individual body (as in self-punishment). Each of these instances of punishment is influenced by philosophical theory, which also will be considered.

Feeding in the Family

The first place children experience socialization is within the family. This is the starting point of physical and social development, where values and behaviors are formed. Because children are unable to feed themselves or discern for themselves what is good to eat, many of these norms are communicated to them through food – that is, through the variety and quantity of foods they are given, and the manner in which they are fed. This dependency creates an environment in which parents – by withholding certain foods and enforcing the consumption of others – indoctrinate their children with a particular set of ideas concerning what is physically, socially, and morally acceptable behavior.

Two important contributions to educational theory, Plato's *Republic* (Plato 1969) and Rousseau's *Émile* (Rousseau 1911), provide a philosophical basis for punishing children with food. These works assert that education begins at birth and must involve careful control of the diet. What is good to eat is not merely a matter of health, but also must be considered for its moral quality. A proper diet promotes physical health and develops moral character. Since children are not born with this knowledge, these values must be acquired through dietary education and training. Thus, punishment is intended for moral instruction. It is an act of discipline designed to promote the best interest of the child.

Both the *Republic* and *Émile* endorse food deprivation within the family as a form of moral education. Withholding food cultivates in children the virtue of temperance (moderation) and discourages the vice of gluttony. The idea is that, if left to their own devices, children's appetitive desires will become insatiable, leading to vice, which in turn causes disease for the body and the soul. As Rousseau says, intemperance must be avoided, as it “excites the passions, and. . .in the long run it debilitates the body” (Rousseau 1911, p. 22). Food intake, therefore, must be carefully monitored, and certain foods must be limited or prohibited altogether to prevent moral corruption and disease. Interestingly, both Plato and Rousseau suggest that meat not be fed to children (Plato

1969, p. 372; Rousseau 1911, p. 119); it would seem to fall into the category of what Plato calls the “unnecessary appetites”: foods that are harmful to the body and a “hindrance to the soul” (Plato 1969, p. 559b, c). Through “early correction and training,” these harmful tendencies can, and indeed must, be suppressed (Plato 1969, p. 559a–c).

Conversely, enforcing the consumption of particular foods is equally important for a child’s moral development. Just as there are foods that should be avoided, there are those that ought to be encouraged in moderation. These acceptable foods belong to Plato’s list of “necessary appetites,” which are fundamental for life and contribute to a “good habit of body” (Plato 1969, p. 559). The right foods – presumably vegetarian in nature – administered in correct proportions, make for a healthy body and soul (Plato 1969, p. 372; Rousseau 1911, p. 119). These tendencies are not innate in children, who are so often tempted by unhealthy things; thus, the consumption of good foods and manners must be forced upon them. Rousseau believes the diet of children ought to be simple and natural, so as not to “excite their gustatory pleasure but only to satisfy their hunger” (Rousseau 1911, p. 119). And for Plato, a healthy diet produces a well-ordered individual, and ultimately, a just state.

Sometimes food is used to punish children for wrongdoing. In these instances parents may withhold a substance that is wanted, as in revoking the privilege to eat a treat, or they may force the consumption of something undesirable. While these punishments may not be directly related to children’s eating habits, the use of food remains a persuasive technique for shaping their moral character. Plato seems to support these kinds of punishments in his *Protagoras*, where he states, “If the child yield a willing obedience, all is well; if not... treat him like a young tree that is twisted and bent, and try to straighten him with threats and blows” (Plato 1888, p. 325). Plato asserts that punishment is to the soul as medicine is to the body – it cures wickedness (Plato 1888, pp. 478–479; Mackenzie 1981, p. 200). Thus, penalties should be carried out directly through habit and conditioning, and the child should welcome rather than shun punishment because it

heals the soul. Because food is intricately associated with the body, which must be controlled, it is likely Plato would condone the use of food for various disciplinary reasons.

Rousseau, in contrast, prefers more indirect forms of discipline for children. He insists that, “punishment must not be inflicted on children as a punishment, but... as the natural consequence of their bad acts” (Rousseau 1911, p. 65). For example, rather than physically punishing a child for lying, simply allow the ill effects to fall upon them, such as distrust and false accusations. It would seem that Rousseau condones more psychological forms of punishment. Yet when he describes the eating habits of *Èmile*’s future companion Sophie, he suggests a more direct approach. When Sophie took sweets from the pantry as a child, her mother “reproved her, punished her, and made her fast” (Rousseau 1911, p. 291).

Feeding the Confined: Food in Prisons

Throughout history, deprivation, food contamination, and involuntary eating have been common measures of imposing penalties on criminals. Before the nineteenth century in the West, punishments were primarily corporal in nature and often took place in public places. The infliction of physical pain was seen as a retributive measure carried out against offenders in payment for their crimes. Public exhibition was intended to shame and reform criminals and serve as a deterrent to others (Plato 1888, p. 323). The rationale centered on the Platonic notion that control over the body is essential for promoting justice and reducing the incidence of crime (Plato 1888, pp. 504–505; Mackenzie 1981, p. 189). If criminals received any food at all, rations often consisted exclusively of bread and water. Food torture was commonplace. Criminals were deliberately poisoned, malnourished, and even left to starve. Though torture in prisons has been prohibited in recent years, following the establishment of international human rights laws, the use of food for punishment remains a common punitive strategy, affecting prisoners both physically and symbolically.

In *Discipline and Punish*, Michel Foucault examines the emergence of the modern prison system, a phenomenon signaling the shift away from the “public spectacle” of corporal punishment to a more institutionalized, “surveillance-based” system. This new structure, he argues, is not the result of increased humanitarian concern for criminals, but rather a “slackening of the hold on the body” (Foucault 1977, p. 10). While corporal punishment torments the body physically, imprisonment afflicts the body psychologically. The body is now an instrument for depriving the criminal of certain liberties or rights (Foucault 1977, p. 10). At the same time, Foucault questions the total disappearance of corporal punishment. He suggests that incarceration necessitates a certain level of physical pain. Confinement, food rationing, and forced labor, which are regular features of prison life, certainly affect the body.

Foucault’s writings illustrate well the function of what he calls the “punishment–body relation” (Foucault 1977, p. 11). Incarceration is at once both physical and mental punishment. Food works similarly when used for punishment. Even in instances when criminals are fed adequately from a nutritional standpoint, the loss of individual control over their food choices causes them anxiety and robs them of certain liberties. This anxiety is significant. It represents the ability of the institution to exercise power over the criminal through food, with or without the use of nutritional deprivation. For example, in American prisons inmates in solitary confinement are fed with mixed-ingredient compressed foods, resembling meatloaf in appearance and colloquially referred to as “nutraloaf” or “confinement loaf.” These feedings are specifically designed to provide hostile inmates with adequate nutrition while simultaneously serving as part of the punishment (they are said to be tasteless and unappetizing). Most, if not all, prison food is rationed and the frequency and location of meals is strictly regulated. This loss of freedom in eating – what Foucault calls a “deprivation of liberty” – is equal, and perhaps even more agonizing, than the physical pangs of withholding food.

As a result of the mental anguish experienced while in confinement, prisoners often use hunger

strikes to shift the balance of power. Food refusal is a potent physical and symbolic statement for prisoners and a means of regaining some measure of control over their bodies. It is so effective a weapon, in fact, that prison authorities often retaliate by force feeding the prisoners. This act nullifies the prisoner protest and reasserts “proper” authority within the establishment. Questions surrounding the ethical basis of such actions have been widely debated in recent years, as they are viewed as a violation of universal human rights. Is force feeding cruel and inhumane treatment? If not, does it nevertheless violate a prisoner’s right to refuse medical treatment? Consequently, many prison medical practitioners are now required to prove that force feeding is a medical necessity (Lines 2008, p. 30).

Food and Political Punishment

Two treaties drafted by the UN General Assembly – the *Universal Declaration of Human Rights* (1948) and the *International Covenant on Economic, Social and Cultural Rights* (1967) – explicitly state that all humans should be free from hunger and have enough food for an adequate standard of living. Since governments are required to uphold these laws, one of their chief responsibilities is the allocation and protection of food resources. Of the many measures used to secure food supplies, the economic trade of commodities – including agricultural crops and manufactured food products – is among the most powerful and endangering. In the *Wealth of Nations*, Adam Smith asserts that the protection of free trade is “essential to the defense of the commonwealth” and therefore a critical responsibility of the state (Smith 1909, p. 480). Because governments continuously rely on trade with other nations for food supplies, political and economic relations between them are critical. When these relations are strained, food availability often is threatened and social instability ensues. Food thus becomes a stage upon which political and economic struggles for power are acted out. Edible commodities are transformed into political weapons used to

punish opposing nations or to manipulate the state's own people.

Defending citizens from the violence of other nations is, for Adam Smith, the first duty of government. He argues that this protection can only be carried out by means of military force; that a well-trained standing army ought to be maintained continuously, not merely during times of war; and that the provisioning of supplies is an obligation of the state (Smith 1909, pp. 468–471). Smith emphasizes the strategic importance of keeping an army fed during battle and encourages the use of billeting for provisions when war is fought at a distance (Smith 1909, pp. 340–341). He maintains that fleets and armies are supplied not with gold and silver, but with consumable goods (Smith 1909, p. 338). The trouble is many of these goods are often requisitioned from civilian populations. In this sense, food can be used as a punishment against civilians during times of conflict. War theorist Carl von Clausewitz also recognizes how food scarcity can be a “special principle of destruction” during warfare (Clausewitz 1908, p. 212). Historically, armies frequently experienced greater casualties due to inadequate food, illness, and fatigue than from active combat (Clausewitz 1908, p. 212).

Denying enemies access to food in wartime can be as destructive to human life as the use of military arms (Wallenstein 1976, p. 277). These measures may be carried out directly, as in a military invasion, or indirectly, as in trade embargoes and economic sanctions. During active combat, armies throughout history have employed various food strategies, both offensively and defensively, including scorched-earth campaigns, slash-and-burn tactics, blockades, and pillaging. The Union blockade on Confederate ports during the American Civil War is an example of an offensive strategy where food restrictions effectively starved the South into submission. Perhaps the most well known of these defensive strategies is Napoleon's invasion of Russia in 1812, where his *Grande Armée*, who expected to forage for subsistence, were forced to retreat as a result of Russia's deliberate destruction of food resources. Clausewitz rebuked Napoleon for his strategic

logistical failure to secure food supplies for his marching armies (Clausewitz 1908, p. 214).

While the deliberate destruction of food resources and forced starvation are now considered crimes of war, governments continue to utilize various food-targeted measures to punish enemies, mostly through trade embargoes and economic sanctions. Even blockades are permissible under international law, so long as they do not impede civilian access to adequate food or destabilize food production in war-stricken areas. The US embargo with Cuba, first imposed in 1960 and still active today, has been among the most long-lasting, severe, and controversial food-related trade prohibitions in modern history.

Governments sometimes assert political power over their own people by limiting access to food. While restricting food availability is not always intended for harm, the consequences can be devastating, especially for the disadvantaged. Food rationing and dramatic price inflation – which may be attempts to protect food supplies – can lead to famine, food shortages, hunger, and starvation. In *Poverty and Famines*, Amartya Sen questions the view that famines are caused by “food availability decline” (FAD). Rather, famines are the result of widespread failures in food distribution and entitlements (Sen 1991, pp. 154, 162). “A person's ability to command food...depends on the entitlement relations that govern possession and use in that society” (Sen 1991, p. 154). For Sen, the fact that famines can “thrive” even at times when there is no particular shortage of food is an indication that famines are more directly linked to entitlement inequalities. Conversely, the notion that certain population groups can prosper while others starve, as in the Bengal famine of 1943, provides further evidence of Sen's “entitlement approach.” Moreover, governments – in attempting to offset the damages of famines – may inadvertently, or perhaps deliberately, deprive particular population groups access to adequate food.

Occasionally, nations punish citizens ruthlessly and deliberately with food. The reasons for carrying out such measures are various, but some examples are political despotism, forced collectivization, and genocide. The Ukrainian

famine of the early twentieth century is among the most notorious of state-sanctioned famines in modern history. Millions of peasants were starved to death as a result of Stalin's forced collectivization of grain production. What had once been the "breadbasket of Europe" became the graveyard of the poor.

As retaliations against the state, hunger strikes can be highly effective social protests. Just as in prisons, self-imposed deprivation wields a great deal of symbolic power. When individuals feel the government has acted unjustly or has violated a personal liberty, they may choose to deprive themselves of nourishment to generate social unrest and attract attention to their cause. While nonviolent in nature, these protests typically need to be calculated, collective movements in order to have significant impact. Individuals acting in isolation rarely have the ability to manipulate change and shift the balance of power. There have been some occasions, however, when hunger strikes staged by individuals have achieved success, as in the hunger strikes of Mohandas (Mahatma) Gandhi in the first half of the twentieth century. As a well-liked public figure with an established following, Gandhi's political protest played a key role in bringing India independence from British colonial rule.

Feeding Body and Soul: Food and Self-Punishment

As a substance taken into the body, food not only nourishes and sustains, it also becomes a physical part of oneself when it is consumed. In this sense, an individual's relationship to food is quite personal. Furthermore, the particular foods one chooses and the manner in which these foods are eaten serve as a means of distinction, differentiating one individual from another in terms of body composition, cultural background, social class, and so forth. Yet the very eating habits that mark one's individuality are shaped and regulated by culture. In other words, society defines for the individual what is suitable to eat by attributing moral values to foods and eating behaviors – e.g., some foods are good, whereas others are forbidden. These normative standards are

constructed to promote physical health and, perhaps even more importantly, to control social behavior. A person must moderate his or her eating habits in order to meet these norms. When one fails to do so – by eating the wrong foods or consuming too much or too little of the right foods – one's physical health, social position, and very character are at risk. Consequently, individuals punish themselves with food through dieting, fasting, and eating disorders in order to correct dietary wrongdoings and conform more closely to social standards.

While dieting certainly addresses matters of health, it is equally concerned with the cultivation of moral virtue. Consider how often dieting is a punishment for "bad" behavior such as poor or indulgent eating. In fact, dietary health itself hinges on one's ability to eat the "right" foods in the "correct" manner and proportion. A healthy person is believed to exhibit the virtue of self-control, whereas one who eats excessively or is overweight is deemed unhealthy and therefore lacks character. Thus, a person diets in order to achieve moral propriety and to exhibit the culturally prescribed qualities of dietary health. Restricting food intake following weight gain or a period of "bad" eating is a self-punishment for wrongdoing, a means of moral correction. Controlling the appetitive desires is a recurring theme throughout the works of Plato, who views the illusory temptations of the body as an enormous threat to the higher, eternal values of rational thought. He argues that the diseases of the soul originate from a disordered body, and the inflated desire for physical pleasure – such as that for food and drink – is the "greatest disease of the soul" (Mackenzie 1981, p. 176). Therefore, the body must be self-disciplined in order to produce the virtue of temperance, which leads to a well-ordered and healthy soul. Aristotle's theory of moderation echoes these sentiments, where control over the appetite is not only virtuous, but also necessary for the good life.

The religious tradition of fasting transforms self-imposed dietary restrictions into a spiritual discipline. Religious fasting is viewed as heightening spirituality and bringing one closer to God, creating more time for spiritual contemplation,

improving self-control, and building resistance to physical suffering. Though typically performed as an act of devotion, fasting also occurs during times of mourning or is used for repentance. The religious doctrines of early and medieval Christianity share many of the philosophies of Greek ethics concerning the body. Gluttony is classified as a cardinal sin, and the corresponding virtue of self-control appears among the “fruits of the Spirit” in Galatians 5:23. Tertullian extols the virtues of fasting in his apologetic writings, where he exclaims, “the temptations which attend upon fulness and excessive indulgence of the belly are stifled by abstinency” (Tertullian 1854, p. 281). He refers to fasting and other afflictions of the body as sacrificial offerings to God (Tertullian 1854, p. 345). St. Augustine’s *Confessions* recall his own struggle with dietary temptations, where food was both the “medicine of nourishment” and a snare of lustful wickedness (Augustine 1943, pp. 251–252). The fight against the desires of the flesh was, for Augustine, a daily war where fasting “brings the body into subjection” (Augustine 1943, p. 251). Teachings renouncing the flesh became so prolific in the early church that an enormous wave of men and women devoted their lives to abstinence, giving rise to the ascetic movement. Many of these believers were venerated as saints for their extreme dietary demonstrations, and many of them starved. Nevertheless, fasting for early Christians was seen as a means of achieving salvation. Their deprivation was seen as virtuous, as a victory over the flesh, and a sacrificial example for other believers.

In the age of nutritional science, austere food practices once celebrated for their piety have given way to what are now diagnosed as eating disorders. Individuals suffering from anorexia nervosa and bulimia punish themselves with food (or the lack of it) because of the severe anxiety they feel concerning their physical bodies. Both disorders are centered on issues of control, where extreme eating behaviors – such as self-induced starvation or bingeing and purging – are attempts to master the unruly desires of the appetite. In *Unbearable Weight*, Susan Bordo argues that eating disorders are the symptoms of persistent cultural pressures on the individual body to

achieve idealized forms of beauty. These illnesses are not bizarre psychological abnormalities, but rather the “the crystallizations of culture” – they are characteristic representations of “much that is wrong with it” (Bordo 1993, pp. 35, 141). As an overwhelmingly female phenomenon, anorectics and bulimics suffer from the “tyranny of slenderness” that has become so prevalent in contemporary culture. Fueled by constant multimedia messages, these women are “relentlessly driven by an ideal image of ascetic slenderness” (Bordo 1993, p. 152). Though these disorders have only recently been “discovered,” Bordo illustrates that they have existed, in one form or another, throughout history. Anorectics and bulimics typically express an ideology – exhibited by feelings of bodily entrapment and depictions of the body as a prison – that bears remarkable similarity to the mind–body dualism of Platonic and Augustinian ethics, where the spiritual realm is of higher, eternal value and the physical realm is temporary and illusory. The desire to free the soul from the body – which is a common theme in these illnesses – is actually a very old concept. Therefore, eating disorders are extreme representations of a much broader cultural issue concerning food consumption. Society, through cultural norms, exerts immense control over individual eating patterns.

Summary

This entry explores the manifold ways in which human feeding practices may be used – physically and symbolically – for punishment. As both a biological need and a central aspect of personal and social identity, food can be a potent weapon in the control over one’s own body and the bodies of others, whether it is used in the family, in the prison, and in the political sphere or is self-inflicted. Throughout the ages, these practices have been supported by philosophical theory, which may account for their continued prevalence. Yet increased interest in human rights has begun to call into question the use of food for punishment. The issues are many-sided and complex and deeply embedded in culture, so the

solution to these concerns is not always simple. As societies shift, what was once an acceptable food practice might later become controversial. The same is true for punishment. History has demonstrated that food remains a compelling instrument for punishment – it simply assumes new forms of expression in the midst of change. Nevertheless, it is most ironic that what is supposed to nourish the body is so often used to control it.

Introduction

This entry explores race and racial identity as they pertain to food and eating in the United States. Race is a fundamental organizing principle of American society that structures all forms of social, cultural, and political life. In the humanities and the social sciences, race is primarily

understood as a social construction that is evolving and historically contingent. Despite the shifting nature of race, since the advent of New World slavery, there has remained a salient racial hierarchy in the United States, which has consistently placed whiteness at its apex.

Food practices are implicated in “fields of relationships, expectations and choices, that are contested, negotiated and often unequal” (Watson and Caldwell 2005). Food and the sociocultural act of eating have been significant markers of racial identity throughout colonial and American history and remain central to the process of racialization in contemporary American culture. Conversely, the study of race is critical to understanding food and cuisine in the United States. This entry explores food/eating culture and racial identity as inextricably linked and sees them symbiotically constructing one another. This entry explores various tensions and discussions within food studies and examines the various historical, social, and cultural dynamics involved in food production, consumption, and circulation as they construct race from a transnational perspective.

This entry in particular will pay attention to the correlations between African American identity and race from a historical perspective and will present a loose chronology of some of the major ways by which the racialization of African descendants has occurred in the United States through food and eating. In addition, attention will be given to the correlation between a racialized immigrant identity and food, also from a

historical perspective. However, because the topic of racial identity and eating is so expansive and such a format inherently limits the ability to cover the topic in its totality, this entry does not devote exhaustive attention to the ways that other communities of color and ethnic populations have been racialized through food. In particular, there is a long complex history, which has received a depth of academic attention, of racializing East Asian, South Asian, Mexican, Hispanic, Caribbean, and European ethnic populations through food. Because of the constraints of this entry, the role of food in the racialization of these communities of color will only receive a brief cursory introduction in this entry.

Defining Race, Racial Identity, and Racial Discrimination

This entry begins by laying out common definitions of race and racial identity before discussing the specific role of food and eating in the process of racialization. Throughout American history, race has been incorrectly understood in popular discourse and the sciences as inherently biological. Coinciding with the advent of slavery, European colonialists constructed a common understanding that certain races, primarily non-Anglo-European, Indigenous peoples of the Americas and African descendants were innately inferior based upon a set of essential physical characteristics such as skin colors, head shape, hair type, and body type, among others. Despite the inaccuracy of this understanding, the notion of racial inferiority based on physical traits has been used throughout colonial and American history to justify a racial hierarchy that privileges Anglo whiteness. This fraught understanding of race has, since colonial contact, been widely influential in all aspects of American social life including the physical bondage of slavery, criminal justice, segregation, the biological sciences, economics, politics, popular culture and sport.

More recently, in the humanities and social sciences, as well as partially in popular rhetoric, the notion of race as biological has been largely dismissed. It has been proven by academics,

including but not limited to Michael Omi and Howard Winant, Charles W. Mills, Paul Gilroy, bell hooks, Robin D.G. Kelley, and David Roediger, among numerous other critical race theorists and critical philosophers of race, that there is no genetic difference among races (Omi and Winant 1999). Rather, it has been demonstrated that there is as much genetic variation within races as there is across them. Race is now commonly defined as a system of categorization that is socially constructed by complex social, cultural, economic, and political forces. This understanding of race is known as *racial constructivism* and asserts that even while race is no longer understood as biological, it came into existence and continues to exist because of human decisions and cultural trends.

However, as cultural theorist Robin D.G. Kelley makes clear, race was never simply about banal categorization, but rather was intended by Anglo colonists to function as a system of supremacy where one group, specifically Anglo whites, dominates and oppresses others. As Philosopher Charles Mills's seminal text *The Racial Contract* asserts, systems of racial oppression in the United States are predicated on a racial contract, which he defines as a set of meta-agreements between whites to categorize all non-whites as subpersons of inferior moral, cultural and legal status relation to whites (Mills 1999). This "contract" gives whites the right to exploit nonwhites and deny them opportunities commonly provided to whites. Mills makes clear that, for most of the modern era, whites have had as little obligation to recognize the rights of nonwhites and as such Anglo whites have utilized race in complex ways to privilege their place at the apex of a distinct racial hierarchy since the advent of New World slavery.

In addition, scholars have defined race as historically contingent and evolving and have made clear that the nature of racial identity, the process of racialization, and the nuances of race relations change and shift over time. However, with each evolution and change in the articulation of race (be it legal, political, cultural, social, or economic), racial categorization remains tied to a similar and replicable racial hierarchy that continues to privilege whiteness over all other racial identities.

Racial discrimination and racism are systems of advantage based on race, which constitute a set of evolving cultural messages, institutional policies, practices, beliefs, and actions of individuals. It is commonly understood that racism and racial discrimination require both power and privilege and involves the creation or reproduction of structures of domination based on essentialist categories of race. In addition, racism and racial discrimination not only operate on an individual level in small-scale social interactions but rather are pervasive logics that are deeply embedded in societal institutions such as the state, legal system, criminal justice, urban space, and popular media, among countless other large sociopolitical institutions.

Defining Eating Culture

While the definition of food is fairly commonly understood as any substance consumed which provides nutritional support for the body, this entry includes in that definition all “processes that make animal, vegetable or mineral into something to eat and then all that is involved in what happens next to bodies and societies” (Slocum 2011). The definition of eating and eating culture is far less widely understood. Eating culture is the complex set of discourses, representations, and social practices that surround the act of eating, ingestion, and food consumption (Tompkins 2012). This entry not only correlates race with food as a material object but also examines the social and cultural practices that surround eating and eating culture. In addition, it is important to note that eating provides unique means through which racialization is performed, because unlike other racial enactments, when eating, food literally gets ingested and fills the body on a material, physical, sensory, and affective level.

Food and Eating in the Historical Construction of Racial Identity

Sugar, Colonization, Slavery, and Race

Perhaps the first and most important correlation between food, eating, and race is the role of the

sugar trade in the advent of New World plantation-style slavery and the distinct racial hierarchy that simultaneously emerged. In the sixteenth century, sugar was a highly sought-after commodity and luxury item throughout Europe. It was used not only as a condiment but also for medicine, rituals, ceremonies, and display. In the seventeenth century, sugar began to grow in popularity and emerged as a staple of most European diets by the eighteenth century. As such, European sugar traders actively sought out a new means of sugar production to meet this increasing demand, hence increasing commercial value of sugar. Because of the warm and moist climate, the European colonial accusations in the Caribbean, Latin America, and Southern United States were ideal for year-round growth of sugar cane and sugar production. As a result, European sugar producers built sugar plantations throughout these regions in the seventeenth and eighteenth centuries. Throughout the eighteenth, nineteenth, and twentieth centuries, the vast majority of the sugar consumed in Western Europe was produced in the Caribbean and other areas in the New World (Mintz 1986).

However, because the growth, harvesting, and production of sugar were so time and labor intensive, these plantation owners needed a viable source of inexpensive labor in order to produce sugar as cheaply and efficiently as possible. European colonists first turned to the colonized Indigenous population as a source of forced labor on the large-scale sugar plantations. However, because of their familiarity with the land (and ease of escape) and their dwindling population numbers (in large part because of the violence of European colonization), the Indigenous populations proved to be an insufficient labor source for sugar production. Thus, European plantation owners quickly turned to the African slave trade as a means to ensure a captive labor supply for the dangerous, violent, and intensive process that was sugar production. As a result, throughout the Caribbean, Southern United States, and Latin America, thousands upon thousands of West Africans were forced into bondage and held captive as a labor source on the European sugar plantations of the colonial world.

The life of a slave on a sugar plantation was brutal. Because sugar production was so physically demanding (involving cutting of the cane, crushing the cane, boiling, and sugar processing, mixed with the searing humidity of these regions) and slave owners were so violent, many African slaves died during the sugar production process. Especially in the Caribbean, the rate of slave death was extremely high. This high rate of slave death fostered an increase in the number of West Africans brought to the New World in bondage to work in sugar production and fostered the expansion and growth of the West African slave trade, bringing thousands more West Africans to the Americas and the Caribbean in bondage to work in the European colonial sugar plantations.

Many historians and critical race theorists have tied the emergence of plantation-style agriculture, in this case for sugar production, to the advent of a distinct racial hierarchy that defines Africanness or blackness as inferior and places Anglo whiteness at its apex. In order to justify the brutal captivity that was slavery on a sugar plantation, Europeans needed to justify the bondage and continual violence against African slaves, and hence, the category of “black” was constructed as subservient and inferior to Anglo-European whiteness. To exploit slave labor in such a brutal fashion, European colonists associated blackness with racial and biological inferiority and imagined slaves innately subhuman and determined for such bondage. This form of slavery required exploitation based on racial logic, and the emergence of such a distinct racial hierarchy can be linked directly to plantation-style sugar production and the increased consumption of sugar throughout Europe.

African American Foodways During Slavery

Decisions about what to eat are of utmost importance to preserving cultural and racial identity across geographic spaces and temporalities. Colonization and the slave trade caused an enormous amount of cultural exchange, blending, and hybridization that affected every aspect of cultural life, including food. This process of exchange, known as creolization, laid the foundations for African American food in the United States.

African American food has its roots in the Igbo and Mande communities of West Africa because of the large number of slaves sent to the New World from this region (Opie 2008). Several foods that are common among African American communities have historical incarnations in this region of Africa. For example, grits are closely related to millet served in West Africa. Another example, fried chicken, which has a long historical and racialized connection to African American identity, has culinary roots in the West Africa palm oil-fried guinea hen. In addition, African slaves brought many foods such as rice, sorghum, coffee, okra, watermelon, and the “Asian” long bean to the Americas during the transatlantic passage to the Americas (Carney and Rosomoff 2011).

Since slaves were thought of as a valuable economic commodity, slave owners throughout the Americas often provided slaves with a daily provision of food which provided enough nutrients to sustain life and maximize their ability to function as a bonded source of labor. Although slave diets varied greatly throughout the Americas, slave provisions in the American South often included an allotment of grain or other simple carbohydrate and a weekly ration of salted meat (Eisnach and Covey 2009). However, these slave provisions were often lacking in size, variety, and nutrients, and as a result, slaves found creative ways to supplement their food intake. In the United States (both before and after the American Revolution), slaves often maintained small garden plots adjacent to slave quarters (such gardens were not very common in the Caribbean) where they grew foods common to West Africa. This allowed slaves not only the ability to supplement their nutritional intake but also an important means to maintain their cultural connections to the African diaspora and their West African cultural and culinary roots. Hence, these foods became an important means with which slaves maintained cultural and racial identity despite the brutal violence of their living and working conditions in American plantation bondage.

What’s more, foods brought by slaves to the Americas not only became crucial to the assertion of African and African American identity but also

became highly influential to American culinary identity. Because it was common to have slaves work in the slave owners home or “big house” as cooks and domestic servants, many of the African culinary staples and cooking techniques mixed and blended with European cuisine to form new distinct American culinary cultures. Many of the foods that are commonly understood by most Americans today as “Southern”, corn bread, biscuits, fried chicken, pork dishes, greens, gumbo, and jambalaya, are the direct result of African slave foodways and its central role in shaping Southern cuisine. Another prominent example includes barbeque, which is a central cooking style in the United States, which also remains central to African American cultural identity. Barbeque as a cooking style is a derivative from a combination of Indigenous pit grilling techniques, African grilling traditions, and African American cookery both before and after slavery (Warnes 2008). Many of these African American and distinctly Southern culinary traditions spread throughout the United States as a product of the Great Migration, which resulted in further culinary mixing between black and white populations. As a result, culinary cultures that remain central to African American identity, most notably barbeque, became common in places such as Kansas City, St. Louis, Chicago, the Midwest, and various cities in the Northern United States.

Post Slavery, Reconstruction, Jim Crow, Civil Rights, and Soul Eras

Much like during slavery, in the postbellum era, African Americans utilized cooking and eating as a means to maintain the African American community and diasporic connections, as a form of cultural resistance, and as a means of creatively subverting white cultural domination. However, during this time, white Americans found ways to associate African Americans with certain foods, in particular chicken and watermelon, as a means to correlate blackness with inferiority and demeaning tropes such as laziness, buffoonishness, and propensity for criminal activity.

Minstrel shows were a form of American entertainment popular in the United States from the

post-Civil War era into the early twentieth century. Minstrelsy consisted of musical and dance performances, comic skits, and variety acts that were performed by white people in blackface (and also to a lesser extent African Americans in blackface). Blackface is a form of theatrical makeup used in minstrel shows, vaudeville, and film in which performers paint their faces black using makeup or burnt cork in order to create an offensive stereotypical caricature of an African American. The minstrel show often began with brief burlesque performances and comic shorts in the early 1830s and emerged as a full-fledged form in the next decade. By 1848, blackface minstrel shows were widely popular and considered the most important popular culture entertainment of the time. They gained popularity, in part, by translating formal art such as opera and Shakespearian theater into popular terms accessible by a general audience. Minstrel shows and later vaudeville theatrical performances remained popular into the mid-twentieth century, and the tropes common of these theatrical performances were utilized in the early years of the film era.

Minstrel shows caricatured African Americans as dim-witted, lazy, buffoonish, superstitious, happy-go-lucky, musical, and innately criminal. Common tropes in these performances included “the mammy,” a nurturing and subservient African American housekeeper and childcare provider; “the Uncle Tom,” a subservient, religious, and passive older African American man; “the buck,” a larger menacing and sexually dangerous powerful African American man; “the Jim Crow,” a buffoonish, lazy, criminal, and dirty African American man; and “the coon,” a mockery of African American men that was an arrogant, ostentatious figure who dressed in high style and spoke in a series of malapropos and puns that undermined his attempts to appear dignified.

Food and eating were often utilized in these theatrical and film performances to construct problematic and damaging tropes that associated African Americans with buffoonish, criminal, and dim-witted behavior. In particular, minstrel performers utilized watermelon and chicken to portray black Americans as less than human for the purpose of justifying systematic discrimination

and a racial hierarchy that privileges whiteness. While it is unclear where these stereotypes originated, numerous primary sources chronicle black resistance to slavery through day-to-day acts of defiance. Stealing from the slave master is an example of such forms of resistance, and it seems logical that food would be among the most desirable items to have been stolen, especially since slave provisions were often lacking. Both chickens and watermelons would have been commonly available on Southern plantations, and while the theft of these items can be seen as a challenge to slave master authority and a sign of slave agency, it is plausible that the stereotypical correlation between African Americans and these food items could have emerged at this time.

Minstrel performances, vaudeville, film, and consumer culture utilized images of chicken and watermelon to produce a constant stream of anti-black imagery by depicting African Americans as constantly eating, craving, stealing, and feverishly pursuing both chicken and watermelon above all else. This racist imagery produced by and sold to white Americans presented African Americans as unkempt and in tattered clothing, buffoonish, innately criminal, speaking in a highly stereotypical dialect, living in extreme poverty, lacking any ambition for education or social power, and largely content with their impoverished standard of living. Chicken and watermelon were utilized in these cultural forms to portray African Americans as animalistic and so subhuman that it was not education, wealth, or power that satisfied black ambition, but rather within this negative imagery African American desires were problematically directed solely towards chicken and watermelon. The “coon” character especially was depicted in such popular cultural performance as illiterate and lazy, content to waste the day either eating watermelon or chasing chickens (often unsuccessfully).

Three specific ways that both chicken and watermelon were utilized in popular performance and consumer culture to perpetuate racial oppression and antiblack sentiment warrant specific attention. First, African American men were depicted as constantly attempting to steal either chicken or watermelon in both minstrel

performance and popular ephemera. Often these attempts were foiled by the overseer or slave master because of the African American’s own blunders. It was also common to see the chicken personified and escaping capture by easily outwitting the reckless, ludicrous, and fatuous coon character. Such images were always decontextualized from a reality both during and post slavery where many slaves and sharecroppers faced high levels of poverty and often stole to supplement their food supply or as an active act of resistance against racial oppression. Rather, chicken and watermelon were used in such imagery to construct a discourse of the black male as innately criminal, an association that in many respects remains today. Second, often these popular culture productions often literally depicted African Americans as chickens. This literal construction of black man as chicken closely correlates African American identity with that of an animal, and in the case of chicken, an animal that is thought of as crude, witless, and only valuable in the eyes of white Americans as a source of food. Finally, by correlating African American men with chicken, in particular the rooster, popular culture was constructing a discourse on black male sexuality that viewed the black man as having an animalistic and uncontrollable sexual appetite, especially for the perceived purity of white femininity (often associated with the hen). Correlations between chicken and the black male body in part functioned to create a stigmatization and fear of black sexuality, which also remains salient in popular rhetoric today (Williams-Forson 2006).

It also should be noted that both chicken and watermelon were not simply utilized by white performers in minstrelsy, vaudeville, film, and consumer culture to construct detrimental racial tropes but also that these foods were appropriated by African Americans to resist racial domination. Not only did slaves and post slavery blacks steal such foods as a means to challenge the authority of Southern whites, but African American men and women utilized the sale of food in the ante- and postbellum eras to assert their collective agency and autonomy. In particular, “waiter carriers,” female African American cooks, sold food

along railroad lines to train passengers to assert themselves as valid members of the nation-state through the demonstration of their economic value, build community, continue cultural traditions, and travel, all of which challenged existing racial (and gendered) power structures of the time (Williams-Forson 2006).

Food has also remained a crucial part of African American sociopolitical activity and organization during the Civil Rights, Soul Eras, and beyond. In the 1960s, the Black Panther used a free breakfast program to critique white American imperialism and domination by sustaining their own African American community through radical food spaces. This breakfast program advocated a revolutionary politics that rejected governmental food aid, which the Black Panther Party saw as a means to pacify and make docile the African American community. For the Nation of Islam, restricting one's diet and the consumption of healthy food protects against the consequences to one's health and domineering culture of a racist society. The Nation of Islam rejected soul food, especially foods like pork and chitterlings, because of their direct correlation to slavery and the diets imposed by slave masters. Other food activists during the Soul Era embraced soul food claiming it as a statement of "racial pride precisely because it reclaims food previously despised – those animal parts that slave had to eat because their owners would not" (Slocum 2011).

Colonizing Native Diets

It also should be noted that European colonists and white American expansionists also used food to colonize Indigenous peoples throughout American history. Practices such as forced farming on Indigenous reservations, European eradication of the wild buffalo population, and highly processed US food provisions became a means of imperialism, colonization, and racial oppression enacted by Europeans and white Americans against Indigenous peoples. For example, the US federal government, in efforts to oppress and control the Indigenous people of the American plains, forced these populations to ranch, slaughter, and consume of beef, instead of

hunting wild bison, which had been a common practice of Plains Indians for generations (Wise 2011). This food-based colonization has resulted in high levels of obesity, diabetes, and other diet-related health problems among many Native peoples. However, throughout the history of settler colonization, Indigenous peoples throughout the United States have fought back against this food-based colonization and made a radical claim of autonomy by decolonizing their own diets and restoring traditional foods, culinary techniques, and foodways to Indigenous cultural life. One notable contemporary example is the consumption of wild rice by the Ojibwa peoples of Minnesota.

Racialization Beyond Blackness: Diaspora, Culinary Nostalgia, and "Ethnic Spice"

As mentioned above of African diasporic foodways, for immigrant groups throughout US history, food has functioned both as a means for racial othering and oppression and as a means for diasporic cultural continuity and the maintenance of a distinct ethnic identity. And while this entry does not detail the history of immigration and food in its entirety, it is necessary to point to some important trends in the ways which immigration implicates food and ethnic foods in racial hierarchies and racialization throughout US history.

"Nostalgic gastronomy," or the process by which one recreates their memories of home through food, has allowed immigrant groups, often in the face of oppression, alienation, and isolation, to bridge a "sensual gap" between the homeland and the United States by engaging in many of the culinary practices and cultural traditions of their respective home countries (Slocum 2011). While there is great culinary hybridization and exchange in the American culinary landscape, working against efforts to normalize their diets and firmly entrench them within mainstream American culinary habits, immigrant populations have pushed back and reasserted their cultural identity through the continued production, consumption, and sale of foods, dishes, and products unique to their cultural identity. For example, as Krishnendu Ray and Anita Mannur detail, the

Indian-American community has utilized food, articulated through either the literature or the restaurant industry, respectively, to maintain South Asian identity and remain culturally connected to the Indian subcontinent (Ray 2012; Mannur 2009).

However, despite the importance of immigrant foodways to the continuation of ethnic and cultural identity, immigrant foodways in the United States are often associated with the lower end of the culinary (and racial) hierarchy through a discursive connotation with toil, labor, and uncleanness. On the other hand, European cuisine has often been understood within mainstream culinary discourse for its refinement of taste and culinary skill (Slocum 2011). In fact, ethnic food itself is a racialized term that has been used to “invoke the ‘exotic’ nonwhite other and that some ethnic foods are indeed more ‘ethnic’ than others.” As such, the foods of racialized immigrant populations have often been used by Anglo whites to the maintenance of an articulate racialized cultural hierarchy (Padoongpatt 2011). For example, in the mid-eighteenth century, white American nativists often associated the Chinese population with the consumption of certain foods (most commonly rice but even sometimes cats and rats) as a means to claim that Chinese immigrants were disease ridden, dirty, weak, and unfit to enter into the larger American body politic. Despite the fact that food, specifically the prevalence of Chinese restaurants, has remained a central communal node and important source of labor for the Chinese American community, Anglo whites have used a discourse of Chinese cuisine as “foreign” and “exotic” to perpetuate the orientalist exoticization of Chinese culture and continually render them outside of American normative cultural identity.

Mexican Identity, Borderlands, and Food

One example of this simultaneous process of racial othering and the maintenance of a distinct cultural identity through nostalgic gastronomy can be seen in the cuisine of the Mexican/Mexican American community. As Jeffrey Pilcher’s several texts point out, food has been central to the development of Mexican nationalism and the

emergence of a distinct Mexican identity in the face of European and American imperialism (Pilcher 1998). Popular Mexican foods such as corn, tortillas, and the working-class staple taco essentially fused European and Indigenous Mexican cuisines together, resulting in a new hybrid cuisine. This cuisine which merged parts of European and Indigenous culinary cultures together formed a new cuisine which came to be seen as representative of a distinct and emergent Mexican identity. These “Mexican” foods expanded into the United States with the annexation of Texas in 1845, the cession of Mexico in 1848, and the subsequent influx of Mexican immigrants across these newly established borders. The continuation of Mexican culinary traditions by Mexican populations in the United States offered the ability to remain connected to that Mexican ethnic and national identity by populations no longer living in what was politically considered part of the Mexican nation-state. For the Mexican American and Mexican populations, food became a way to maintain cultural and ethnic identity despite the shifting and permeable nature of the national borders and changes in national governing bodies.

However, much like Chinese cuisine before it, Mexican cuisine was used within popular American rhetoric as a means to distinguish Mexicans as outside of white American cultural identity and hence in a marginalized place in the racial hierarchy. In the 1940s, 1950s, and 1960s, especially in Southern California, Mexican food was associated with the influx of working-class migrant labors entering the country as part of the *bracero* program (a federal program which encouraged the immigration of seasonal farm laborers from Mexico). Mexican food, just like Chinese cuisine before it, was exoticized and racialized in this context. Mexican food came to be commonly understood by white Americans in Southern California as cheap, dirty, and of a lower culinary and cultural status as compared to European cuisine. Hence, this rhetoric surrounding Mexican cuisine hardened the racial tensions in California during the mid-twentieth century (which boiled over into physical violence during the Zoot Suit Riots). According to Pilcher, it wasn’t until Glen Bell

opened several fast-food Mexican-themed eateries, known as *Taco Bell*, that Mexican food began to gain popularity outside of Mexican ethnic enclaves. Pilcher argues that Taco Bell succeeded not just by selling fast food but rather by selling a form of exoticism that allowed white Americans to sample Mexican cuisine without crossing the lines of segregation in the 1950s in Southern California, hence making it “safe” for white Americans to explore (a highly corporate and hybridized version) Mexican culture (Pilcher 2008). Therefore, food allowed Mexican and Mexican Americans to remain culturally connected to Mexico, while it was simultaneously being used to racialize Mexicans as outside of and inferior to normative American cultural identity.

Food and White Racial Privilege

It also should be noted that within the racial ideologies of late twentieth-century liberal multiculturalism, white Americans have often utilized the consumption of “ethnic food” as a means to rearticulate their cultural and racial privilege. Common among progressive white food-conscious consumers of the late twentieth century is what Lisa Heldke defines as “cultural food colonialism,” a white American passion for eating, cooking, and appreciating food that is rooted in a racist colonial thirst for adventure, authenticity, and novelty. As Heldke and other food scholars have noted, this logic reaffirms white privilege and white normativity by simultaneously rendering ethnic food as foreign and by securing the “food adventurer” as willing to collect and publicly display their experiences of ethnic and racial difference (Heldke 2003). White Americans have utilized orientalist logic to construct many ethnic foods from communities of color as peculiar, bizarre, unfamiliar, and even sometimes dangerous. Eating ethnically often becomes a performative act that progressive white consumers utilize to express a sense of bravery and adventure, as well as an adaptability and openness to experiencing the supposedly exotic cultures of immigrant groups. What is crucial, however, about eating ethnically for white consumers, however, is not just that the act is

predicated on constructing ethnic food cultures as exotic or even grotesque (which is part and parcel of a nativist racializing project that throughout US history has understood immigrant bodies as unclean and disease ridden) but also how that consumption is then called upon to articulate a very particular type of ethnic cultural cachet and reinforce the cultural privilege of one’s own white (privileged and normative) identity.

In summary, while white US citizens have used the taste of foreign foods to racialized immigrants of color people from Asian, African, and South American populations as exotic and hence racially other, these diasporic populations have also relied on cuisine and taste to discern and maintain their ethnic identity and assert their cultural validity within the dominant white normativity of mainstream American culture.

Food Justice and Contemporary Correlations Between Eating and Race

This entry concludes by detailing some of the contemporary correlations between eating and racial identity by paying particular attention to contemporary debates surrounding food justice as well as by exploring the racial practices of contemporary alternative food movements. Communities of color often have not embraced alternative food movements (including the organic movement, local food movement, and slow food movement), which many of these movements’ proponents envision as a solution to the widely documented ills of industrial agriculture. However, this is not the result of an African American community unsympathetic to the movements overarching goals of improving food quality and national health, but rather because of the use of color-blind rhetoric and exclusionary practices by active members of movements. These movements often articulate white ideals of health and nutrition as well as present a whitewashed vision of farming that erases the past and present of an American agricultural system predicated on racial exploitation. The US agricultural legacy is tied to an institutional racism that forced African Americans

and Mexicans into agricultural labor and removed Indigenous people (Mexicans and African Americans as well) from their land (Guthman 2008). However, the practitioners of alternative food movements present a vision of an idealized agricultural past that is free of such racial oppression. The primarily white members of alternative food practice seldom see the color-blind and whitewashed agricultural history as problematic, in part because of their own place of racial privilege and in part because of the pervasive normativity of their white racial identity. However, black activists are beginning to make a claim for the centrality of an African American space within alternative food movements, and it is increasingly common to see people of color at the center of alternative food practice, especially in inner cities throughout the United States.

Due to the long-term effects of institutional racism, African Americans disproportionately live in economically disadvantaged neighborhoods that lack access to quality, healthy, affordable food. These neighborhoods, known as food deserts, often lack an adequate number of (if any) quality supermarkets. It has been proven that such urban spaces have spatial and structural characteristics that result in poor diets, which have a detrimental impact on African American health and lead to disproportionately high levels of diet-related disease in the black community. The pervasive rhetoric has been that these health effects are not structural but rather a direct result of unhealthy characteristics of African American cuisine, in particular soul food, which critics argue is high in saturated fats and cholesterol. However, African American scholars, activists, and cookbook authors such as Bryant Ferry and Breeze Harper have written against such negative associations and have used food to combat the health problems of the black community by making radical claims against the colonization of the African American diet. Rather, it is important that the lack of access to quality food and the detrimental health effects that result in black communities are seen as a direct result of racialized institutional policies that have historically left African American communities at a disadvantage.

As expressed in the film *Soul Food Junkies* by scholar and activist Marc Lamont Hill,

There is no better example of racism in the twenty first century than the relationship between black people and access to healthy foods. People think about racism as an individual act of discrimination from one person to another, but that's not what it is about. It is about systems, it is about structures, and it is about institutions. And the fact that black people live in neighborhoods where they can't get access to healthy food choices, and white people can get healthy food choices, that is classic text book racism. You want to wipe out an entire generation of people, you want to engage in a kind of twenty first century genocide, all you have to do is continue to do what we have been doing; which is deprive black people access to healthy food. (Hurt 2013)

Summary

Race is defined as an evolving and historically contingent social construction predicated on the ability of Anglo whites to assert, promote, and maintain the ideal of white supremacy against all other racial groups. This racial hierarchy is predicated on a racial contract that underwrites and guides all major institutions and cultural practices in the United States and thus assigns political, economic, and social privileges based on racial identity. Despite the shifting nature of race, since the advent of New World slavery, there has remained a salient racial hierarchy in the United States, which consistently places whiteness at its apex.

Food and the sociocultural act of eating have been significant markers of racial identity and central to the process of racialization and the maintenance of distinct racial hierarchy throughout American history. Since the advent of New World slavery and the emergence of sugar plantations in the New World, food has been used to correlate communities of color, in particular African Americans, with a marginalized position in this racial hierarchy. However, communities of color have also used food as a means to assert their agency and self-determination, thus challenging their position within the dominant racial structure. Some of the major correlations between African American identity and food include sugar

consumption, plantation slavery, and the advent of racial hierarchies; transatlantic slavery and food in the construction of American cuisine; common African American tropes as constructed through food in postbellum popular culture; the role of food in radical black politics; and the role of race in alternative food movements and contemporary food justice issues. In addition, food and eating have been central in the process of colonization and racialization of Indigenous peoples; in the racialization and exoticization of immigrant populations, including but not limited to Chinese, Thai, and Mexican communities; and in the construction of white privilege. As such, this entry has maintained that food/eating culture and racial identity have been inextricably linked and have symbiotically functioned to construct one another throughout American history.

Ready-to-Use Foods (RUFs)

Lisa F. Clark¹ and Jill E. Hobbs^{2,1}

Food assistance; Food security; Local regional procurement; Malnutrition; Public-private partnerships

Introduction

Ready-to-use food products (RUFs) are used to address malnutrition and micronutrient deficiencies as part of international food assistance strategies. RUFs are any foods that are formulated to be eaten out of the package without cooking, adding water, or any other type of preparation. They are part of international food assistance strategies that usually involve UN (United Nation) agencies like the World Food Programme and UNICEF. They are used in emergency humanitarian situations and have more recently been used to fill the nutritional gap in situations where individuals are not able to secure appropriate, nutrient-rich foods in their everyday diets. RUFs are also used to prevent the negative health consequences of micronutrient deficiencies in children, which include stunting and wasting. This article explains how RUFs are used in international food assistance strategies and identifies challenges that have arisen with respect to the supply and distribution of these products. The relationship between the UN Millennium Development Goals and RUFs is explained, and the challenges in sourcing these products through locally and regionally based supply chains, together with the role of public-private

partnerships (P3s) in commercializing these products, are outlined.

What are RUFs?

Two types of RUFs exist: ready-to-use therapeutic foods (RUTFs) and ready-to-use supplementary foods (RUSFs). RUTFs are intended to contain all of the energy and nutrients necessary to treat children from 6 to 24 months of age for severe acute malnutrition. The health in the “first 1000 days” of a child’s life is considered to be crucial for proper human development. Most RUTFs are lipid-based products, meaning that the majority of energy in the product is derived from fats. Typically, RUTFs are in paste form and usually consist of peanuts, vegetable fat, sugar, dairy ingredients, and a micronutrient mix. RUTFs can also come in the form of biscuits and compressed bars. A good example is Nutriset’s *Plumpy’Nut*, which is widely procured by UN agencies to treat severe acute malnutrition in children.

RUSFs, on the other hand, are meant to provide only part of the daily energy and nutrient requirements of recipients. Like RUTFs, they come in the form of pastes but are designed to treat moderate acute malnutrition as well as treat and prevent micronutrient deficiencies. The quantity given to an individual is determined based on their health status and age. RUSFs can also be given to pregnant or nursing women to prevent micronutrient deficiencies and promote health in home-based care programs.

Controversies, Challenges, and the Rethinking of International Food Assistance Strategies

Over time, the way in which the international community approaches food assistance has evolved, affecting the context within which RUFs are developed, produced, and distributed. The focus on food security enshrined in the UN Millennium Development Goals provides the institutional backdrop to this context, while a move to LRP of food aid products (in preference

to transoceanic food aid shipments) represents the tangible outcome of the shift in approach, with the use of public-private partnerships (P3s) as a component of the new approach.

Setting the Path: The Millennium Development Goals

Established in 2000, the Millennium Development Goals provide a more nuanced interpretation of sustainable development to include a focus on poverty reduction, food access, education, gender equality, health, and environmental sustainability. Goal 1 is to “eradicate extreme poverty and hunger” in the world by 2015, while reducing child mortality is Goal 4, and improving maternal health is Goal 5. The food security and sustainable development mandates of the Millennium Development Goals have two related foci: addressing the long-term socioeconomic impacts of micronutrient deficiencies and reducing poverty (Clark and Hobbs 2015). Technological and economic interventions are recognized as important in achieving these goals. Technological intervention features transfer of agricultural production technologies with the objective of scaling up local supply chains, while economic interventions involve approaches to improve upon how RUFs are produced and distributed (Guimón and Guimón 2010).

Millennium Development Goals 4 and 5 are components of a longer-term nutrition agenda which includes an emphasis on addressing undernutrition in the “first 1,000 days” of a child’s life, where a lack of micronutrients such as zinc, vitamin A, and iron can have irreversible life-long health consequences for children from conception to two years of age, including stunting and wasting. These conditions, in turn, have serious long-term implications for health, including susceptibility to infectious and chronic diseases and impaired intellectual development (Arimond et al. 2015). To effectively address food security within the context of sustainable development goals, therapeutic food products designed to treat undernutrition must be safe and nutrient rich to aid in fighting micronutrient deficiencies, accessible and affordable to key populations affected by undernutrition, as well as commercially viable. Recognition of this broader context has changed how food assistance strategies

are designed and how therapeutic food products are produced and delivered to those in need (Clark and Hobbs 2015).

The 2030 Agenda for Sustainable Development replaced the Millennium Development Goals in 2015. The Agenda consists of 17 goals and 169 targets to address poverty, climate change, and social inequalities. The goals outlined in the Agenda are organized around the concept of “integration,” which encourages stakeholders to collaborate on strategies working toward actualizing the “Zero Hunger Challenge.” The “Zero Hunger Challenge” is the new food security initiative taken up by UN organizations. The goal is for all people to have “100 % access to adequate food all year round” (Herforth 2015). It also includes working toward achieving “zero stunting and good nutrition, and access to adequate food for everyone at all times; sustainable, inclusive and resilient food systems with no loss or waste of food; and support for smallholders, especially women and young people” (UN 2015).

A shift in mandates from UN agencies includes addressing the socioeconomic and ecological causes of food insecurity such as poverty, gender inequality, lack of education, and climate change. In regard to food assistance, UN agencies now prioritize sustainable development, scaling up existing agricultural markets in developing countries and technological transfer in programs they administer and/or with which they are affiliated. Development focus has shifted to supporting donor countries and organizations that invest in the necessary infrastructure to help developing countries participate more fully in existing markets. The goals are to serve domestic markets, while also participating in international markets.

The Shift to Local Regional Procurement (LRP) of Food Aid

What emerged under the auspices of the Millennium Development Goals is a more nuanced understanding of long-term strategies to address food insecurity and the role of RUFs and RUSFs as components of that strategy. The shortcomings of overreliance on transoceanic food aid were brought into sharp focus by the humanitarian crisis that unfolded in the aftermath of the Indian

Ocean tsunami of 2004. Transoceanic food aid models were woefully underequipped to respond to the serious disruptions in transportation networks that occurred. Humanitarian assistance was delayed because the international food aid regime was based on a model that predominantly consisted of donor countries manufacturing food aid products and shipping finished products to regional storage facilities, or shipping RUFs as emergency humanitarian situations arose. Donor countries realized that this model of food aid and assistance needed to be reviewed, leading to a shift toward LRP strategies incorporating cash-based and voucher programs to reduce exclusive dependency on single-sourced products. LRP is based on the concept that as many components of the supply chain as possible should be regionally or locally situated to increase the speed with which food assistance is distributed to those in need, as well as facilitating broader food security goals tied to sustainable development.

The World Food Programme, UNICEF, and other international aid agencies now pursue LRP as the preferred method of sourcing raw materials for RUTFs, with the result that, by 2012, 45 % of the RUTFs purchased by UNICEF were produced in Africa for distribution in African countries (UNICEF 2013, p. 1). A number of studies have concluded that locally and regionally based RUTF supply chains are more efficient and cost-effective than those heavily reliant on transoceanic transportation networks, deliver more culturally appropriate food and have the potential to bolster local marketing channels, support farmers, and improve food quality and safety, thereby contributing to several Millennium Development Goals (see, e.g., USGAO 2009; Lentz et al. 2013).

Nevertheless, the shift toward more diversified approaches to sourcing RUTFs and RUSFs has met with some challenges. The enforcement of procurement contracts for emergency food aid products in new markets has at times proven problematic, and the LRP approach has received criticism for its potential to distort local markets, driving up food prices in times of shortage (Lentz et al. 2013). While a popular approach and a policy priority for international aid organizations, it is recognized that LRP is not necessarily a

panacea nor is it unequivocally the most effective and economically viable means of organizing supply chains for RUFs. Evidence in this regard is mixed. Based on survey data, Violette et al. (2013) find that recipients of locally procured (likely more culturally appropriate), food aid products are generally more satisfied than the recipients of US-sourced foods. Using case study analysis of transoceanic versus LRP food aid procurement strategies in two different countries, however, Harou et al. (2013) find that neither strategy dominates the other across all criteria examined. The authors find that LRP tended to perform at least as well as transoceanic shipment with respect to timeliness, cost, market price impacts, food safety, satisfying the preferences of recipients and benefiting smallholder suppliers, but that the extent to which one strategy outperformed the other varied across contexts and countries, suggesting that the context and program objectives are key considerations.

Investigating the concern that LRP could drive up local food prices and contribute to food price volatility in food aid source and recipient countries, Garg et al. (2013) provide an empirical analysis of the relationship between food prices and their volatility, LRP and distribution of food aid for several commodities across several countries. The analysis finds, for the most part, that LRP and distribution activities do not have a statistically significant relationship with local price levels or with food price volatility. Nevertheless, a few exceptions exist where local price impacts were apparent; these tended to be associated with food distribution rather than procurement activities, highlighting the importance of market monitoring where LRP strategies are in effect.

While LRP strategies can help scale up existing markets through investments in infrastructure such as transportation networks and create new value chain opportunities by sourcing raw materials from local producers, nascent market institutions pose challenges in operationalizing LRP supply chains. Institutions that are taken for granted in a well-functioning developed market economy are often absent or poorly functioning in a developing or transition economy (Hobbs 2007). Financial institutions, such as an effective

commercial banking system, a credible commercial legal system for enforcing contracts, marketing institutions that facilitate price discovery and risk management, commodity grading and quality certification institutions that facilitate transactions over time, and geographic space, are all prerequisites to efficiently functioning agricultural markets and the establishment of successful local supply chains for RUFs. Inadequate quality measurement (grading) institutions and price discovery mechanisms, uncertainty over contract enforcement, or poorly defined property rights raise the transaction costs of doing business, stifling investment incentives and hampering the development of sustainable local supply chains. LRP strategies for RUFs may require improvements to storage, transportation, and distribution infrastructure to assist in the development of efficient agricultural markets over time and space and the creation of successful value chain relationships within those markets. The establishment of commodity grading standards, certification, and other food standards that provide credible quality signals reduce the transaction costs for RUF manufacturers of identifying reliable suppliers or of sourcing inputs of a known quality.

The longevity of the shift to LRP strategies for food assistance over transoceanic shipments of food aid is also a function of donor countries' commitment to this approach. Food aid shipments of physical agricultural commodities from donor countries, while often addressing a pressing humanitarian need, are also a potential avenue for the disposal of surplus agricultural production, thereby distorting recipient country markets. In December 2015, at the World Trade Organization (WTO) Ministerial meeting in Nairobi, a decision was reached on export competition that may have unintended consequences for the use of food aid as a surplus disposal mechanism (Kerr 2016). WTO members reached an agreement to prohibit the use of export subsidies for agricultural products. Previously used as a mechanism to subsidize the disposal of surplus agricultural products at low prices on world markets, export subsidies distort market prices in importing countries and are considered harmful to agricultural producers in those countries. The Nairobi Ministerial Declaration

also needed to address the opportunity to use food aid shipments as a means to circumvent the ban on export subsidies, while allowing food aid shipments to contribute to food security where needed. Kerr (2016) suggests that, while the rules agreed in Nairobi allow food aid to continue to contribute to food security, they fail to adequately address the nefarious use of food aid to dispose of agricultural surpluses. With the closing of the door to export subsidies as a means of surplus disposal, the incentives to use transoceanic shipments of food aid as a means of surplus disposal may increase.

The Emergence of Public-Private Partnerships (P3s)

The development of LRP strategies for food assistance has been accompanied by an emphasis on public-private partnerships (P3s) as a means to develop, produce, and distribute RUFs. As the name suggests, P3s are a collaborative effort between the public and private sectors aimed at achieving a mutual objective which utilizes the core competencies and complementary expertise of the stakeholders, and in which each stakeholder takes on a degree of risk (financial, technical, and/or organizational) and responsibility in the partnership and in all activities related to the product (Clark and Hobbs 2015). In the context of the development and distribution of RUFs for food assistance, P3s can involve private food companies, local agro-processors, governments, and nongovernmental organizations (NGOs).

In food assistance strategies focused on the development of RUFs to address malnutrition and micronutrient deficiencies among at-risk populations, a P3 approach implies modifying the traditional business model to foster cooperative information exchanges between the holders of knowledge and technological know-how and processors of ready-to-use products located in developing countries. Often, the emphasis in these partnerships is on finding ways to keep the value-added stages of the supply chain as local and disaggregated among agricultural producers as possible, while technical transfer and humanitarian assistance objectives feature in investors' willingness to participate in place of

(or alongside) profit-driven motives. In this regard, private sector motivations for participation may also be part of a company's broader corporate social responsibility (CSR) platform and driven by a desire to improve corporate reputation among a broader consumer base (Clark and Hobbs 2015). Skeptics of private sector involvement in humanitarian efforts caution that CSR mandates must go beyond the goal of winning "good corporate citizen points" to using a firm's resources to maximize the social benefits flowing from their investments (Byiers and Seravesi 2013).

The commercialization of RUFs faces challenges with respect to striking the appropriate balance between maintaining the incentive for private sector firms to innovate and invest in the development of new RUFs formulations and ensuring access among vulnerable communities to products with widespread health benefits. The French company Nutriset developed a peanut-based RUF product known as *Plumpy'Nut* in 1996 which was found to be more effective at relieving severe acute malnutrition than earlier corn-soy blend RUF formulations. Given its nutritional advantages, the *Plumpy'Nut* innovation was considered a major breakthrough in international food assistance products. When there was discussion surrounding how *Plumpy'Nut* could be manufactured closer to the point of consumption through regionally or locally oriented supply chains (using locally grown peanuts), however, questions arose regarding intellectual property rights (IPRs) and the ability of manufacturers in developing countries to access the rights to produce a RUF that had been shown to alleviate human suffering. In the early 2000s, the vast majority of *Plumpy'Nut* procured by UN agencies was purchased from the company's factory in France. Controversy brewed over Nutriset's pursuit of patent protection over what some claimed to be a fairly generic formula for nutritional nut paste (Bakhsh 2012). In response, Nutriset argues that it is imperative to license facilities to ensure that products carrying the *Plumpy'Nut* label meet the safety and quality standards associated with the product. Protection of IPRs through licensing also creates a stronger incentive for firms to innovate, encouraging the development of new

formulations for nutritionally enhanced foods. Thus, a conundrum exists: how to maintain private sector commercial incentives to continue investing in the development of new formulations for RUFs, while ensuring wider access to nutritionally superior products among vulnerable populations.

Partially in response to growing public criticism, in 2005 Nutriset established the "Plumpy Field Network," a P3 initiative consisting of eight agro-processors located in a number of countries (including Ethiopia, Niger, Sudan, Burkina Faso, India, Haiti, Madagascar, and the USA) licensed to produce *Plumpy'Nut* for food assistance purposes. By 2011, approximately 25 % of *Plumpy'Nut* was produced in developing countries (Nutriset 2016). Nutriset also participates in technological transfer and skills training for employees from their *Plumpy Field Network* members. It has increased the number of its agreements with small landholders and has developed information exchange relations with universities to improve the agricultural technologies used in key inputs.

The development and distribution of RUFs through the use of public-private partnerships focused on LRP strategies typically features an international organization partnering with private agro-processors in a developing country to manufacture RUFs, while working with international food companies and donors to facilitate technological transfer at different stages of the supply chain. Food assistance agencies frequently play a pivotal role in the development of supplementary food products, working with various levels of government, private foundations, private businesses, and local food producers and processors to produce the RUFs for local markets. Fundamentally, food insecurity is driven by poverty, and typically the cost pass-through to consumers covers less than half of the costs of production, necessitating subsidization of ready-to-use foods through P3 arrangements involving nonprofit agencies and companies willing and able to accept the risk of financial loss and engage in technical transfer initiatives (Lybbert 2011).

Two examples serve as illustrations. Ethiopian company Hilina Enriched Foods produces

RUSFs using locally sourced chickpeas produced by cooperative farmer unions. Established in 1998, and now co-owned by Nutriset which holds a 49 % share in Hilina, the company specializes in the processing of foods specifically designed to address malnutrition and other micronutrient deficiencies. The company supplies enriched food products to various UN agencies including UNICEF and has produced Nutriset's *Plumpy'Nut* since its establishment, sourcing up to 70 % of the ingredients locally (Clark and Hobbs 2015). The company is part of the "Plumpy Field Network" and benefits from information, expertise, and technological transfer from Nutriset.

Guts Agro Industry is another agro-processor located in Ethiopia producing a chickpea-based RUSF for the domestic market, as well as for the World Food Programme. The company received assistance from USAID to expand its production facilities (grain separator, mill, roaster, mixer, and packer) to process chickpeas sourced from a large number of small landholders in three cooperative producer unions and is involved in a series of projects and collaborative partnerships with international agencies to develop and supply RUSFs (Clark and Hobbs 2015). Challenges faced by these types of companies include poorly functioning commodity markets for sourcing raw materials of a known and reliable quality, exacerbated by inadequate storage and transportation infrastructure between spatially dispersed markets, capital constraints, access to affordable food processing technologies, and capacity building among key value chain participants (farmers) and at the processing level.

While many P3 initiatives exist which emphasize LRP strategies to address food insecurity, skepticism remains regarding the economic sustainability of products that have uncertain or unpredictable demand patterns and little opportunity for generating profit. Nevertheless, the P3 model appears to be an essential component of food assistance projects given strained public resources and the lack of financial and human capital resources to access, let alone develop, beneficial technologies and innovative distribution models.

Summary and Conclusion

Ready-to-use food products address malnutrition and micronutrient deficiencies as part of international food assistance strategies and include ready-to-use therapeutic foods for severe acute malnutrition, particularly in children, and ready-to-use supplementary foods to ameliorate chronic malnutrition as well as treat and prevent micronutrient deficiencies. The 2030 Agenda for Sustainable Development continues to focus on poverty reduction, food access, education, gender equality, health, and environmental sustainability in addressing food insecurity. Consistent with these goals, international food assistance has shifted from reliance on transoceanic food aid to the development of LRP and distribution strategies, often based on public-private partnerships between food companies, local agro-processors, NGOs, and domestic governments. While challenges persist in food supply chains served by fragmented infrastructure and underdeveloped market institutions, ready-to-use foods remain an increasingly important component of the evolving food assistance landscape.

Introduction

Recipes are the instructions for preparing an item or description of a process to accomplish a final product. They also represent a style of literary writing described as “discourse” and can be structured in multiple different ways, depending on the product, the author, or the audience. Recipes are featured in many different formats, such as books, blogs, memoirs, websites, textbooks, newspapers, magazines, and still by word of mouth. Each of these sources targets a different audience, which allow the recipes to be shared with a large variety of people. Some may target professionals, while others write for home cooks. This entry will follow the history of recipes and look at the different sources of recipes such as cookbooks, websites, blogs, magazines, and other sources. It will discuss the different types of formats to write a recipe and delve into the ethical questions that arise from the writing and sharing of recipes.

History

Recipes did not begin as a culinary source. Their beginnings were of a medical root. *The English Housewife*, written in 1615, was one of the first publications to contain written recipes, or “receipts,” geared to the housewife. It used food ingredients as medicine, from both a curing standpoint and a preventative one. The wives of the farmers needed to know how to cook food, since they used cooking as a method of preventing many illnesses caused by unsafe water sources

used for crop irrigation. Housewives needed to be intelligent and learned enough to be able to follow the written procedures, but not smart enough to bypass doctors. Doctors became the first recipe authors, of sorts, as they wrote down ingredients and procedures for women to care for the family; these included medicinal uses of food and food as prescribed lifestyles (Knight 2012).

In Roman times, around the first century, mothers taught their daughters how to prepare the foods commonly consumed in the home. This method of handing down recipes was common for many centuries, all the way through the nineteenth century, when literacy finally began to increase within female populations. When the recipes were first written, they did not follow the same guidelines or structure as modern recipes. In many cases, there were no lists of ingredients or any specifics on the quality or amounts required to produce a recipe with a consistent outcome. The instructions had people working off of descriptions of the end result of the product without including measured quantities. Descriptions such as add enough flour to make the dough stiff were meant to provide enough guidance to prepare food. Even though the instructions were written down, there was still a practical or oral aspect that must have occurred in order for the recipe to be passed down successfully. A person who prepared the item had to really understand how much flour is enough to make the dough stiff and how stiff the dough must really be. This made the recipes less accessible to people outside the family circle (Arnold-Ratliff 2011).

The early twentieth century began to see more formalization of a recipe. There were new tools introduced to the home and to the market that simplified the process of having real measures and also new methods of distributing recipes (Arnold-Ratliff 2011). However, in the 1920s and 1930s, in the time of the industrialization and depression, published recipes showed off an unethical approach in being published. This time was an era of the growth of industries, gadgets, and processed foods. The recipes published, many times were created by the companies of these food products or gadgets, made to sell what was needed to make the recipe perfect, thus making the recipe

more about the use of the product, than the cooking of the meal (Wajda 2008).

Women's magazines of the early twentieth century featured recipes for the housewife to produce in her own home; they were also the perfect source to publish recipes laden with hidden advertisements for women to buy processed foods and products that advertisers wanted to sell. The manufacturers and producers of fast food and convenience products began to advertise the lack of time for women in the household to cook and did that not only through the products but through the recipes of easy-to-make, fast food in the home. Many times, these were advertised as such in their titles, by including phrases such as easy to make or fast within the titles of the foods. In addition, recipes began to include suggestions of tools to use within the recipes that would also help to speed up the process, continuing the effort by manufacturers to sell. This made a recipe less of a cooking guide and more of a consumer marketing campaign.

Recipes in magazines, however, continue to be popular since then due to their style of writing and the fact that they are embedded within other topics that attract women. Whether it is fashion, news, or gossip, women's magazines feature recipes that target the type of reader. The recipes within magazines have attracted readers since the late nineteenth century; these now included more precise measurements and procedures that could be followed by a person, even if they had not before seen or tasted the food. Not only were the recipes published in the magazine itself, but the tradition of printing recipe cards for subscription began. Women signed up for a publication, which included both a magazine and recipe cards sent to the home in small collections. Some publications also included the wooden box to organize the recipes in. These recipe cards became more than just a way of sharing recipes; they are now a part of nostalgia and to many a diary of loved ones passed down through generations. Recipe cards spattered with grease, dough, or batter tell the story of a family. *Martha Stewart Living* magazine still prints recipe cards and also has more modern approaches such as applications and websites to accompany their printed magazine (Arnold-Ratliff 2011).

In the early twentieth century, a new cookbook genre became popular with the rise of immigrant cookbooks written due to nostalgia. Those far from home continued to learn their cooking heritage and traditions that had been lost or forgotten since moving far away from their homeland and, in many cases, their families. Many of these cookbooks are written in the form of community cookbooks, which are not only often a memoir filled with recipes, but one that is written from many different perspectives and which tell different stories, since they are a compilation of the recipes of a myriad of families. This was also a good way to share the one attachment that people tend to long the most when migrating, the food. Replicating the eating habits that in many cultures also include the traditions of eating as a family and form the bond between family members was important to immigrants. Writing it down was, in part, to keep the tradition alive and also to tell the story of their family and migration. In many cases, these hid a deeper story or context that would have been seen as unethical or illegal to share in the motherland. The cookbooks were a way of integrating recipes into a critique of the social, political, or economical context of a country, by writing about the food of their homeland in the language of the country they moved to, sharing experiences about life and culture in their home country.

Community cookbooks became a new way to share recipes, usually benefiting a good cause. However, this genre made it harder to leave out an ingredient or change the product, since many community cookbook projects were advertised "real" recipes that were tried and true. Due to this, the publishing of these recipes in these books attached the name to the reliability of a recipe. This became a form of "contract" which made it necessary for the recipes to be shared honestly (Kelly 2012).

Through the evolution of society, recipes have marked societal changes that changed households. Before the introduction of refrigerators, freezers, and stoves into the household, recipes commonly included procedures that described how to prepare and serve food without these devices. As the more modern implements were

introduced into the home, recipes began to change in their procedures, teaching housewives how to properly prepare meals that made use of new kitchen gadgets. So, though the recipes and cookbooks are not themselves history books, their contents reflect the historical changes from the time, allowing historians to use them as historical sources (Kelly 2012).

Recipes also mark family histories. As recipes are passed along from one generation to the next, they usually are labeled with the name of the person passing along the recipe or the events in which they were usually served. As families have welcomed other members and grown, recipes change and are modified, new ingredients are added, and different procedures are tested, until the result has become a newer, more modern version of a family classic. As families have become multicultural, the recipes have managed to record the societal changes. Many have also initiated food traditions for communities, which have also evolved through time, but have become part of what represents that community (Kelly 2012).

Recipes can be a way of showing societal needs and changes, since recipes are created for many different reasons. They can be as a source of need to feed one or many, a way to wisely make use of ingredients when resources are scarce, and creativity and passion for those who may want to explore a new avenue or, in many times, even competition (Heldke 1988). The way a recipe is created can also have a direct correlation with the literacy and socioeconomic levels. People with low literacy rates will not be able to read a cookbook, magazine, or any other written source of recipe. For that matter, many of their recipes continue to be passed down through oral tradition or they must rely on television or other visual format or aural format. It then becomes a matter of expertise and who the audience is. Part of writing a good recipe is making it clear to follow for the target audience. Part of writing a good recipe is making it clear to follow for the target audience.

Community cookbooks were the most popular during the late nineteenth and early twentieth centuries in the United States. The recipes were compiled and made into cookbooks by churches, community centers, aid centers, and other entities,

usually as an item for sale used for fund-raising. They were not considered great culinary resources or pieces of literature, since the authors were common people, usually homemakers, sharing family recipes. They are now recognized as primary sources for the history of small communities, families, towns, as well as gastronomic history. Due to the small circulation within these small communities, they are rare finds now stored in the Library of Congress and most recently scanned and digitized to allow for better record keeping of books in poor conditions due to age (Kelly 2012).

Community cookbooks are a different category of food writing. Each cookbook is written from multiple perspectives, since it usually contains a collection of recipes sourced by a myriad of people from a particular community or group, making the style in which each recipe is written different. Many of these cookbooks were also funded by local businesses in order to cover publishing costs, which in turn entitled them to advertisements within the book. Today, these advertisements provide a historical guide to the businesses and products sold in the different communities where these cookbooks were published. They also give insight on new products in the market at the time when they were written (Kelly 2012).

Most community cookbooks are not heavily circulated. Instead, their main readership is from the local community. Even though the recipes all vary due to the different authors who provide them, they are not all going to provide the same feeling of comfort with preparing the recipe as the cookbooks all written from an author that is usually followed. Instead, those people who have a good cooking reputation within the community will generally provide the recipes that are said to be better in quality by the standards of other community members who spread the word (Tomlinson 1986).

Modern Recipe Sharing: Families, Cookbooks, and Blogs

Until recently, with the popularity of blogs, cookbooks were the main source of recipe sharing. At

first glance, food recipes, in general, appear to be structured in the same way regardless of the source in which it is published. They generally list the ingredients at the top and below and include the instructions with which to put the ingredients together. This can be done in the form of a list or in a paragraph form. Many recipes have been guarded as a family's best-kept secret. Some will share recipes by omitting an ingredient. Oftentimes, that omission will make the recipe falter. Other times, it will just alter the taste slightly, leaving it a little less delicious than its own version. Lying by omission is an unethical approach to recipe sharing, but a common practice, nonetheless. Many times, the owner of the recipe guards it and only gives out parts of the recipe, in order to remain the expert in preparing the dish. The same is true with celebrity chefs who are also on television or are cookbook authors. They want to be able to sell their products, so they will create special "secret" spice mixes that are needed in order to make the dish. These spice mixes are one of the ingredients listed in the recipe. Emeril Lagasse, for instance, has a line of spice mixes needed to prepare his dishes, which are sold in stores. In order to prepare these recipes, one would require his spice mixes (Essence), forcing readers to have to purchase the ingredient within his line of products to have the expected results of the recipe. Because of the importance placed on using that particular ingredient, a reader may steer away from the recipe due to not having such an important ingredient.

Recipe ownership or copyright becomes a legal matter best discussed by attorneys. Some recipes are altered to just meet the requirements to give an author new ownership to a creation. Copyright laws are not as specific or strict when it comes to the publishing of recipes, especially since the advent of the electronic recipe. This is due to the classification of recipes as a list of ingredients rather than a literary publication. Because creations have no protection to copyright laws and recipes have been declared as such, the same is true for them. The increased use of Internet sites as methods of exchanging recipes has had a huge increase on the number of recipes that are shared in blogs and other electronic methods,

allowing readers not to buy magazines, newspapers, and cookbooks they would have otherwise published. Many publications have and will continue to lose audiences due to the use of online journals and blogs, and publishers will cease advertising in such publications, possibly leading many to cease printing (Lawrence 2011).

Cookbooks are one of the most popular forms of public recipe sharing. Cookbook sections in bookstores have continued to grow, flooded by books promising easy-to-make, flawless, gourmet, diet, ethnic foods sure to impress. Others become beautiful coffee table ornaments, meant to feature beautiful pictures of culinary creations or ingredients from around the world. So, though filled with recipes, some of these books will never be cooked from. The recipes will serve more as a literary text, a romance or adventure novel, or a fable, rather than a guide to food preparation. This can be true with many cookbooks, which feature beautiful pictures of the country and its dishes, but recipes that are unlikely to be featured in the common American household. Some of the recipes can be tedious to prepare, requiring more time than is available for the home cook. Others will have recipes of food products not likely to be consumed in the home today, such as organ meats or products that are expensive to buy in a time of troubled economy, such as caviar. However, the role of the woman as the homemaker may still entice her to read a cookbook, even if just as a literary work, reading through the recipes she knows she will not prepare (Bower 2004).

Many modern cookbooks have changed their style. No longer do cookbooks just list a series of recipes and are meant to be a source of culinary instructions as they once were. Many cookbooks now will blend in a story, making them more of a memoir and a cookbook and not just a recipe book. This is especially true of the cookbooks written by authors of blogs or stars of cooking shows, whose stories people have become familiar with and have become part of the family. The Barefoot Contessa Foolproof: Recipes You Can Trust, authored by Ina Garten, Food Network star, for instance, is embedded with first-person advice and instructions as well as personal stories and

photographs of her family and friends, all of whom helped her illustrate the story of her dishes (Garten 2012). Deb Perelman, author of the Smitten Kitchen blog, recently published her first cookbook, the *Smitten Kitchen Cookbook*, which also features photographs of her family embedded with stories of when the recipes were made, written in the first person (Perelman 2012). So, the recipes take the backseat of the cookbook. Many of the recipes featured in both of these books as well as other similar books note that they are adaptations of recipes from other sources and authors, slightly modified to fit a different setting, taste, texture, or purpose.

Though recipes themselves cannot be copyrighted, cookbooks and other media, which contain descriptions, photographs, or any other source of material that may be copyrighted, or a combination of other material mixed with recipes, are eligible for copyright. However, even within the copyrightable material, there is an unethical consideration; the US government copyright page states that if a person has specific ingredients within a recipe that they would not like revealed, they must not include them in the recipe, since copyright applications are public record. This allows for the lack of protection to occur (US Copyright Office 2011).

Recipe blogs, as is the case of Smitten Kitchen, 101 Cookbooks, and many others, have become more than just a collection of recipes. Many of them are known for their food photography. Others have become a new type of memoir. Blogs are embedded with the story of the author and allow for commentary from the community of readers who will also inspire and impact future entries. Also, there are more characters involved, since most of them have an autobiographical style that allows readers a glance into the life of the author. Blogs are nothing more than an electronic journal, one that is published immediately for people to read, allowing the authors to create a following. Many blogs have a female readership and resemble postwar cookbooks. They have become a source of teaching, not only food recipes but the recipe to being a successful housewife or hostess. The recipes will generally follow a common theme, such as comfort foods, vegetarian

foods, healthy foods, or whatever the author's focus may be (Salvio 2012).

Blogs changed food sharing, since a cookbook or recipe within a journal or magazine would include the preparation of the dish itself and maybe a photo of the food. Blogs, however, do not just focus on the food itself but also discuss the process the cook had of getting to the final result, interspersing it with photos, which often illustrate the different steps of food preparation that allowed them to arrive at the final dish. This does not always include a flawless preparation, as is thought to have in many cookbooks. They also tell about the failed attempts to make, what in their imagination would turn out to have a fantastic end result, in the hopes to get commentary from readers on the process or even advice on how to make it work. These become part of the "story," since many food bloggers are professional writers, photographers, or graphic designers, who are amateur cooks and would like to combine one of their hobbies with the one thing they do best, in order to show off their skills in the hopes of being discovered. That blog at that point becomes more than the platform on which to share cooking advice and becomes an electronic portfolio, the beginning of a book proposal of sorts, becoming a gateway for publishers to find talented authors (Salvio 2012).

Many recipe blogs become the easiest sources for home cooks, since many are written by home cooks and housewives, who are constantly reminding readers they too are regular people, as they apologize for lapses in writing due to heavy workloads, travels, or taking care of their families. They have also become a quicker way to search for recipes as well as one that is less expensive. The recipes themselves and the ways their style differ, though most of them take the more modern approach of listing the ingredients first and providing the detailed instructions on how to put them together later.

Each blog has a topic that threads the recipes together depending on the author; this form of e-autobiography focuses on the one aspect of a person's life that is the most important and that becomes the glue that attracts readers (Salvio 2012). Smitten Kitchen focuses on family and

comfort foods enjoyed by adults and children, oftentimes featuring recipes that are quick to make while taking care of a child or more detailed, time-consuming recipes prepared while someone else is caring for the child, while she has time to try out a recipe the author had been longing to make. Another style of blog is the one focusing on a dietary restriction or preference, as is the case of 101 Cookbooks, which is about vegetarian, healthy options, or the myriad of blogs that take us through a person's struggle with chronic diseases, which change their eating and lifestyles forever and allow us to participate on their quest to making the perfect dish that will not taste as if it is missing something.

In one sense, many blogs resemble the cookbooks of the era of the depression and postwar World War II. In those decades of the 1930s and 1940s, women began to work to help support the family while men could not do it on their own or had gone to war. This created the need for two types of foods: comfort foods and those that were quick to prepare. These cookbooks also usually featured more of a memoir style of writing featured within modern blogs (Salvio 2012).

Blogs now feature many published recipes by home cooks and amateurs sharing their story of making it and even sharing what modifications they made to the recipe to make it more to their liking. Sometimes, they will change the name a little bit. Other times, they will simply state adapted from a source or inspired by such other sources. However, there are also the times when none of that is mentioned and the recipe is simply published as one more favorite within a repertoire that now gives readers the idea that the recipe was made up by the author of the blog, who is actually hiding the true creator of the recipe. Though the US copyright laws do not protect the lists of ingredients and claim that recipes cannot be copyrighted due to their constant evolution, the International Association of Culinary Professionals (IACP) has come in to protect the creations and created ethical guidelines that request people to use the aforementioned words of adapted by or inspired by to give proper credit to the originators of the recipes (Gemperlein 2006).

Recipes Writing Styles

The first part of the writing style of a recipe is witnessed when reading the title. Many recipes are not given a name that is realistically describing the dish to be made. Instead, titles are used to be enticing (chewy chocolate chip cookies), sometimes to give information about the author (grandmother's pot pie), and other times to show prestige (best cookies ever). However, these do not tell a lot about the end result of the product. This can create a high expectation, one that is subjective and left to the imagination of the reader; if the end result of the product is below the expectations of the reader, they may feel misled, causing them to believe that they were lied to. Also, oftentimes, there may be ingredients that are unexpected in the recipe from reading the title that may cause a reader to believe that the recipe is not what they were promised. For instance, chocolate chip cookies or brownies may have walnuts in them, but were not listed as walnut brownies or chocolate walnut cookies.

The body of recipes can be written in many different styles. Recipes written in the style of procedural discourse will follow a structure that focuses on organizing the steps. The language will vary depending on the audience the recipe is geared towards. Recipes written for professionals feature jargon and industry terms, while that for the home cook uses more common language understood by nonprofessional cooks. However, whichever the audience, the procedure is very organized by numbering or listing the steps of the procedure. In some cases, keywords within each step can be highlighted, making each of the steps easier to read (Wharton 2010).

Prose is another method of writing a recipe. Some recipes will list the ingredients on the top and write the procedure as prose, with a more densely structured paragraph that goes through the entire preparation process. In the case of Escoffier, the entire recipe is done in prose, not listing the ingredients first, but rather the entire book structured as paragraphs (Escoffier 1979). Because the structure of these is blocky, it does not allow for easy skimming through the steps and will require more time and effort to go through the recipes. In many cases, these will be geared to

professionals or people who enjoy cooking and understand the reward gained from reading through this style of recipe style. Reading through a recipe is not like reading through any instruction booklet, since recipes tend to have a more rewarding result to the process than most other sets of instructions (Wharton 2010).

In addition to how the recipes are written from the instruction perspective, many recipes are formatted in such a way that there is a short description at the introduction of the recipe. This may be within the beginning of a recipe. Many include instructions on serving sizes, serving suggestions, and a little bit about the recipe. Others will include a short introduction that explains the final outcome of the recipe. In the end, these prior instructions and observations may lead to prior misconceptions and judgment for the reader, in many cases causing the reader to try out or dismiss the recipe proposed to the author due to the dislike of the introduction or the instructions provided to preface the recipe. The opposite may also be true with instructions or descriptions appealing to the reader in such a way that they automatically buy into the recipe without even having prepared it yet and will be more likely to try it (Tomlinson 1986).

The choice on how to write the recipe and the style to use, though sometimes not purposefully, will become unethical. Recipes have the tendency of lying, sometimes to protect the integrity and “rights” to the recipe, and others simply by omission. Some families have such pride for the creations that are adored by many and also deeply connected to their roots that they will “take them to the grave.” Many great recipes have probably been lost or forever morphed into a variation, due to people leaving out one key ingredient that no one can know about because it is what made grandma’s recipe the best in the community. Many people find that tradition normal and acceptable; if they gave others the full recipe, the recipe would be able to be replicated, and they would no longer have the right or privilege to be the one to always prepare it (Tomlinson 1986).

The lying by omission occurs oftentimes depending on the audience to which the recipe is targeted. Many recipes, especially those geared to professionals, will include certain ingredients

listed with the measurement of taste. Some books will have recipes that at a glance will seem easy, but as the cook reads on, it has them cooking out of two or more recipes from the cookbook, in order to complete the one recipe intended, making it way more complicated than the original impression. Food recipes are written based on a number of assumptions made by the author; for the amount of food per serving, for instance, when not noted by measure, the recipe will state the number of servings. However, that is relative, since the author will likely not know how hungry the person cooking will be, and if the amount considered to be a serving is not included, the amount may be different than what the cook expected to make (Tomlinson 1986).

Many recipes are a compilation of unfinished instructions; recipes will follow all of the steps of listing ingredients and then the basic description of how those are put together. However, oftentimes, they are done in a way that assumes that all the readers will know basic cooking steps or understand certain qualities about an ingredient that they have not yet been exposed to. When transferred orally, whether by a family member, television, or a demonstration, a person is able to see what the ingredients look like and what the textures feel like and see the thread of every single part of the process answering questions that are left unmentioned and more importantly unanswered to the reader. For instance, many bread recipes will list the amount of flour needed but will oftentimes say more flour for kneading or five cups of flour (or more if needed). The recipe, however, will not specify how much is more, how much flour for kneading, or any other details that will allow a nonprofessional or person who has never had access to bread making to understand the real instruction (Tomlinson 1986).

The incompleteness of recipes is also illustrated within the preparation of the ingredients used within the recipes themselves. Oftentimes, a recipe will include a small instruction within the list of ingredients, oftentimes also differentiating when that preparation must take place with just a small detail. For instance, a recipe may ask a cook to have flour sifted. This automatically makes an assumption that the person will know how to sift

flour; in addition, having the ingredient first, with the comma, then the action, will mean the action must take place after measuring. However, if the instruction read sifted flour, then the action must occur before the ingredient is measured. Many do not know this, since it is not readily explained. Missing the step of preparing the recipe will very easily ruin the dish, which the reader had a high expectation for (Tomlinson 1986).

This follows through into the assembly of the ingredients as well. For instance, recipes that call for creamed butter assume that a reader will know that they should beat the butter with sugar until it has enough air incorporated to it and that it will be creamy and lighter in color. However, many readers will not know that, and others may not have a mixer to facilitate the process already making it deceiving to the reader that they would be able to make the recipe (Tomlinson 1986).

Though the recipes themselves are usually structured with a list of ingredients and a set of instruction, their publication becomes different through the voice of the recipe or the person preparing it. Each of them has an emotional connection for the author and those who read it. They are also more than just an instruction to cook; recipes and their collections are also a part of history, literature, culture, and craft.

Summary

Recipes are instructions to accomplish a final food product. They include the ingredients and procedures needed to prepare them and can be written and formatted in different ways. There are many different sources where they are published, each with a different readership. From cookbooks to blogs, this entry looks at the different writing styles of recipes as well as the ethical considerations behind recipe writing and sharing.

Introduction

The global health foods sector is highly diverse, with product terminology, definitions, policies, and regulations differing markedly across countries. Broadly speaking, the health foods sector is characterized by two categories of products: “functional foods” and “supplements” or “nutraceuticals.” Functional foods have become a fairly widely accepted term to describe nutritionally enhanced foods (e.g., omega-3-enhanced eggs), while nutraceuticals or supplements tend to be marketed in the form of pills, powders, capsules, or tablets. Nevertheless, a universally accepted definition of these terms does not exist, and what may be considered a functional food in one market is treated as a drug in another and a

supplement elsewhere, with different regulatory requirements depending on its categorization. How a product is defined affects its market positioning, the health claims allowed for the product, or even whether it is legal for sale in a particular jurisdiction.

The regulation of health foods is primarily intended for consumer protection, recognizing that consumers need credible information upon which to make informed purchase decisions regarding foods offering health benefits. As the provision of credible information is susceptible to manipulation, governments have regulated health and nutrient content claims which are used to inform consumers about the health benefits of the food or food constituent. These regulatory regimes have evolved independently, creating a confusing and complex global environment for health foods in which both firms and consumers must operate.

Such complexity and variability raises costs for firms trying to export health food products internationally as they must interpret ever-shifting regulatory regimes in individual markets. Firms must assess allowable health claims, product approval processes, testing requirements, and nutritional content labeling requirements. Regulatory differences between countries can create trade barriers; for instance, if an ingredient is permitted in one country but not another, or a health claim is permitted in one jurisdiction but not another.

This entry compares the regulatory environment for the health foods sector in the USA, Canada, the European Union, Japan, and China. The implications for exporting firms of regulatory differences between countries are also discussed.

What are Health Claims?

Health claims are a statement linking the consumption of a food or ingredient to a health benefit. Claims can be either generic or product specific. Generic health claims usually specify a relationship between a food constituent and a health effect and can be claimed by any food product that meets the conditions for using the claim. An example of a generic claim approved in the EU

is “ALA contributes to the maintenance of normal blood cholesterol levels” where any food product listed as an approved source of ALA (α -linolenic acid) in the Annex to the Regulation may use this claim (EC 2015a). Product-specific claims can only be used by products that have undergone a registration process for proprietary use of the claim, which usually specifies a relationship between the food or food constituent and a health benefit, for example, the EU-approved health claim for a water-soluble tomato concentrate and healthy blood flow was granted to Provexis Natural Products in 2014 (EC 2015b).

Beyond generic or product-specific distinctions, health claims are usually further divided into two categories: disease-risk reduction claims and structure/function claims. A disease-risk reduction claim specifies the relationship between the consumption of a nutrient and its effects on mitigating disease risk (i.e., linking the presence of calcium and/or vitamin D and the reduced risk of osteoporosis). Structure/function claims link the presence of a nutrient to normal growth, development, or functioning of the human body (i.e., linking the presence of calcium and/or vitamin D and proper bone structure (Hobbs et al. 2014a)).

Nutrient content claims can also often be made on food and sometimes on supplements/nutraceuticals. Nutrient claims simply describe the presence or absence of a nutrient but tend to infer positive implications for health. In a way, nutrient content claims are implied health claims. For example, a food can claim to be “high in potassium and low in sodium,” both of which contribute to reduced risk of high blood pressure and cardiovascular disease (Hobbs et al. 2014a). Finally, some countries have mandatory requirements regarding the presence of nutrition labeling on processed food products, such as nutrition facts panels that require information be provided in a specific format on the calorie, fat, cholesterol, carbohydrate, protein, sodium, and vitamin content of the food.

Definitions and Health Claim Status

The health food products sector is plagued with a lack of consensus in the terminology used to

describe and define these foods. What may be considered a dietary supplement in one country might be known as a functional food in another and a nutraceutical but not a natural health product (NHP) elsewhere. That same supplement may be considered an over-the-counter product in one country, a prescription drug in another, and banned in a third. As such, a prevailing state of confusion exists in the industry internationally, making informed choices difficult for consumers and complicating the efforts of exporters, regulators, and researchers alike. What follows is a brief regulatory survey comparing definitions and health claim statuses in a select group of countries.

The USA

The USA does not regulate health foods by their definition, but rather by the product's health claims and labeling, which would then determine whether it is governed as a food, a dietary supplement, or a drug and regulated accordingly by the Food and Drug Administration (FDA). Health foods can be defined in a variety of ways in the USA. A "dietary supplement" is defined as vitamins, minerals, herbs or other botanicals, amino acids, and other dietary substances intended to supplement the diet by increasing the total dietary intake or as any concentrate, metabolite, constituent, extract, or combination of these. They are products that are "intended for ingestion in pill, capsule, tablet, powder, or liquid form" and should not be represented for use as a conventional food or as the sole item of a meal or diet (DSHEA 1994). Dietary supplements would be considered nutraceuticals or NHPs in other countries.

While the US FDA does not officially define a "functional food," an accepted working definition is any food that moves beyond necessity (basic nutrition) to provide additional health benefits that may reduce disease risk and/or promote optimal health (ADA 2004). Other common terminology includes "food for special dietary use" and "medical food."

The US FDA allows three categories of permitted claims. Health claims (disease-risk reduction) link a food and a disease or health-related condition (i.e., sodium and hypertension); these

claims must meet a scientific standard to be approved for use by the FDA. Structure/function claims describe a nutrient or supplement affecting the normal growth or function of the human body (i.e., vitamin E as an antioxidant). The FDA does not evaluate or regulate structure/function claims when used for food, and, while it maintains minimal regulations for these claims when applied to dietary supplements, it does not evaluate the claims before use; claims must be substantiated and truthful. Nutrient content claims indicate the level of nutrient in a food and must be approved by the FDA (i.e., the claim "free" can only be applied to calories, fat, saturated fat, sodium, or sugars); unapproved claims are prohibited (Hobbs et al. 2014a).

The regulatory status of a food product is determined primarily by its intended use, its label, and accompanying labeling information, which includes nutrient information, nutrient content claims, and health claims. Manufacturers must therefore make a definitive choice in marketing their product as either a food or a drug, thereby choosing their regulatory classification (Hobbs et al. 2014a). For example, if a functional food product is marketed as a food, it can be regulated as a conventional food product, as a dietary supplement, as a medical food, or as an infant formula.

The US regulatory environment is generally less restrictive toward the approval of new health claims than is the case in many other countries. Qualified claims that have lower standards of scientific evidence for approval, and are usually accompanied by a disclosure statement or less authoritative wording, are permitted for both food and dietary supplements. Structure/function claims on food and dietary supplements do not require premarket approval by the FDA. Nutrient content claims are regulated to roughly the same extent as in some other countries. Nutrition labeling is mandatory and covers a similar number of nutrients (FDA 2013a, b).

Canada

Health Canada (1998) defines a functional food "as similar in appearance to, or may be, a

conventional food, is consumed as part of a usual diet and is demonstrated to have physiological benefits and/or reduce the risk of chronic disease beyond basic nutritional functions” (p. 3). The term nutraceutical was replaced in 2003 with “natural health product” (NHP). An NHP is defined as being “a substance or a combination of substances in which all the medicinal ingredients are made up of natural substances.” NHPs include over-the-counter products used to diagnose/treat and mitigate or prevent diseases such as vitamins and minerals, herbal remedies, traditional medicines, and essential fatty acids (Laeque et al. 2006). NHPs are regulated separately from food or drugs and more restrictively than functional foods. NHPs are subject to product-specific regulations, which reduce spillover benefits and increase incentives for firms to apply to use claims, although they must undergo an approval process.

In Canada, a health claim is any claim that correlates the consumption of a food or ingredient and health. Generic health claims must be from a government (Health Canada) approved list of permitted claims, while product-specific claims must be individually assessed and authorized prior to use. Permitted health claims in Canada include disease-risk reduction or therapeutic claims, structure/function claims, and nutrient content claims, all of which are governed by specific standards and regulations.

Disease-risk reduction claims relate the consumption of food (or a food component) and the risk of developing a diet-related disease, while therapeutic claims suggest that the consumption of a certain nutrient will treat or mitigate a disease or condition or restore or otherwise modify an existing function; an example of which is oat products and lowering of blood cholesterol (Health Canada 2015).

Function claims describe the nutrient’s importance in promoting normal, healthy growth and functioning. Canada maintains a list of approved generic structure/function claims for food and food constituents (i.e., psyllium and regularity), as well as for nutrient function claims applicable to nutrients, vitamins, and minerals (i.e., iron and red blood cell formation and vitamin C as an antioxidant).

Functional foods are allowed the use of approved generic health claims, as well as product-specific claims; use of the latter requires evaluation and approval. The same types of health claims (therapeutic, disease-risk reduction, function) are permitted on NHPs as on functional foods, but each NHP and its associated health claim are evaluated and approved on an individual basis; all NHPs must have a health claim (Health Canada 2006). There are no generic claims for NHPs (Hobbs et al. 2014a).

Any product-specific claims, whether for a functional food or NHP, regardless of function, disease-risk reducing, or therapeutic, require the manufacturer or producer to submit their product and proposed claim for individual assessment, approval, and registration (Hobbs et al. 2014a). Nutrient content claims in Canada must be from an approved list of applicable nutrients which includes energy, fat, or protein, for example. The claims can include terms such as “free,” “low,” “light,” and “lean.” Nutrition labeling, with a mandatory nutrition facts panel, is required for most processed food products.

Canada has a fairly stringent regulatory procedure compared to that of the USA, as evidenced by the smaller list of approved disease-risk reduction claims (although their number has been increasing) and the stronger requirements for the use of structure/function claims. Strict nutrient content claims rules and nutrition labeling rules also suggest a relatively strongly regulated market (Hobbs et al. 2014b).

The European Union

In the European Union, a food is defined as functional if “it is satisfactorily demonstrated to affect beneficially one or more target functions in the body, beyond adequate nutritional effects, in a way that is relevant to either an improved state of health and well-being and/or reduction of risk of disease. Functional foods must be in the form of conventional foods, and they must demonstrate their effects in amounts that can normally be expected to be consumed in the diet: they are not

pills or capsules, but part of a normal food pattern” (Stein and Rodríguez-Cerezo 2008, p. 1).

The European Food Safety Authority (EFSA) characterizes nutraceuticals as food supplements that are concentrated sources of nutrients or other substances with a nutritional or physiological effect. The purpose of use should be to supplement the normal diet. They are marketed in dose form, that is, as pills, tablets, capsules, or liquids, in measured doses or similar formats (EFSA 2010).

With the establishment of a harmonized EU-wide regulatory approach to health claims in 2006, the EU has been assessing generic health claims, establishing one of the world’s most specialized health claims systems. The regulatory stringency of the EU system appears to be high. Many more proposed claims (over 4600) (EC 2015c) have been rejected than accepted. Permitted health claims in the EU are generic structure/function (Article 13.1) claims, product-specific/new/proprietary (Article 13.5) claims, disease-risk reducing (Article 14.1.a) claims, children’s health (Article 14.1.b) claims, and nutrient content claims. Each has accompanying approval processes and requirements of use (Hobbs et al. 2014a).

Nutrition labeling regulations have changed from minimal information provision unless a health claim is made to a relatively new regulation that requires nutrition labeling on processed foods (EC 2013). Food supplements are considered food and can use approved claims; however, food supplements are limited to vitamins and minerals, a significantly narrower band of products than is the case for NHPs in Canada or nutraceuticals/supplements in some other countries (Hobbs et al. 2014a).

Japan

The Japanese government defines “food for specified health uses” (FOSHU) as food that “is intended to be consumed for the maintenance/promotion of health or for special health uses by people who wish to control health conditions, including blood pressure or blood cholesterol”

(MHLW 2010). This definition includes both functional foods and supplements and is referred to as “regular FOSHU.”

In order for a food to be approved as FOSHU, a safety assessment is required, and the efficacy of functional attributes must be established. Furthermore, FOSHU can be categorized beyond regular FOSHU to “qualified FOSHU,” “standardized FOSHU,” and “reduction of disease-risk FOSHU” (sometimes called “specific FOSHU”) reflecting different strengths of assurance regarding the link with health benefits (MHLW 2010). The FOSHU system is largely based upon product-specific health claims (Hobbs et al. 2014a).

Japan does not make a legal or regulatory distinction between “supplements” or “nutraceuticals” and “conventional food.” As such, all FOSHU regulations are the same whether or not the product comes in a conventional food format or a nutraceutical/supplement format. The vast majority of products (over 700) with FOSHU approval are in conventional food form. Indeed, the fact that Japan does not distinguish between conventional food and supplements may prove challenging for foreign firms accustomed to complying with differing regulations for food and supplements (Ohama et al. 2008).

“Food with nutrient function claims” (FNFC) refers to all food that is labeled with the nutrient function claims stipulated by the Ministry of Health, Labour and Welfare (MHLW). As long as the product meets the requisite standards, no further notification to or permission from the MHLW is necessary (MHLW, n.d.).

Both FOSHU and FNFC are, by definition, not only categories of products but also types of health claims allowed in Japan. FOSHU claims are product-specific health claims that require approval prior to use. FNFC claims are comparable to generic structure/function claims in the USA, the EU, or Canada that do not require approval prior to being used on a product. Nutrient content claims are statements applying to nutrients that are useful for healthy living. Nutrition labeling was initially optional unless a health claim is made but became mandatory in 2013 (MHLW 2010).

Japan currently provides an interesting mix between a purely generic system and a purely product-specific one. Although the system is decidedly more product specific, standardized FOSHU lowers the costs to individual firms seeking claims on ingredients with well-established ingredient–health effect relationships. At the same time, there are potentially significant returns to investment for firms wishing to market a new product with health benefits (Hobbs et al. 2014b).

China

The China Food and Drug Administration (CFDA) refers to functional food as health food, defining it as “food with specific health functions that are suitable for consumption by specific groups of people and that has the effect of regulating human body functions without treating diseases” (Patel et al. 2008, p. 4). The CFDA has no specific definition for nutraceuticals/supplements.

China uses a product-specific system of registration to regulate the health foods sector. The use of disease-risk reduction claims, structure/function claims, and nutrient content claims are permitted. The regulatory process in China for achieving approval of health claims is relatively strict, requiring the applicant to conduct studies through an approved agency, in addition to the regular scientific literature review. Only recently has China moved to instituting mandatory nutrition labeling and regulating nutrient content claims to address abuses. CFDA maintains a list of permissible disease-risk reduction claims that firms can apply to use, for example, claims can be made between the approved food and/or food constituent and weight loss, cholesterol (blood lipids) reduction, blood sugar reduction, and blood pressure reduction (Yang 2008). China also permits the use of product-specific structure/function claims. Firms must apply to the CFDA to use claims that specify a relationship between the food or food constituent and specific health effects.

Current Chinese regulations do not make a distinction between nutraceuticals/supplements and conventional food, and there is confusion

regarding the distinction between food and drugs. Yang (2008) reports that less than 0.8 % of functional foods in China are in the form of conventional foods, whereas over 60 % of functional foods are in the form of tablets or capsules. This also means that firms face the same (stringent) regulatory procedure regardless of whether they choose to format the product as a supplement or as a food (Roberts and Rogerson 2008).

Regulatory Issues

Since the introduction of healthier food products, a variety of different terminologies and definitions to describe these products have emerged worldwide. Although broadly referencing foods with health benefits or new attributes, there is a lack of consensus regarding what constitutes a functional food, a dietary supplement, a nutraceutical, or an NHP.

While there is no universally accepted definition for functional food, some common traits are evident in the terminology used across countries. All definitions require that the food product provides benefits beyond that of conventional food; while it should not be perceived as a drug, it should have some physiological functions. In the USA, Canada, the EU, and China (in addition to other countries such as India, Australia, and New Zealand), functional foods are expected to be similar in appearance to conventional food and must provide benefits beyond basic nutrition. Many countries have an official definition for functional foods (the EU, Japan, Canada, China), while others have a working definition only (the USA, as well as Australia and New Zealand). Yet in Japan, for example, no distinction is made between a functional food and a supplement (Hobbs et al. 2014a).

In the USA, foods and dietary components that have health benefits beyond basic nutrition are considered as functional food. In Canada, functional food should be part of a usual diet and have physiological benefits and/or reduce the risk of diseases beyond basic nutrition. In Japan, they are foods containing ingredients claimed to have

physiological effects on humans. In the EU, functional foods are positioned as food with beneficial effects on the human body beyond basic nutrition. China categorizes functional food as food with special health functions (Hobbs et al. 2014a).

Somewhat more consensus exists regarding the definitions of supplements/nutraceuticals. Though the terminology may be different, the underlying intent appears similar among countries. The most common characteristics of nutraceuticals (Australia/New Zealand), NHPs (Canada), dietary supplements (USA), or food supplements (EU) are that they should be sold in measured doses and in the form of pills, tablets, capsules, or liquids, as well as have some physiological benefits or provide certain health benefits (Hobbs et al. 2014a).

The terminology governing these products is evolving and remains contradictory in places. Canada now classifies a nutraceutical as a natural health product, which is equivalent to a food supplement in the EU; this is still often called a nutraceutical in Australia and New Zealand and is equivalent to a dietary supplement in the USA. Confusingly, in Japan (and other countries such as Russia, South Korea, and Taiwan), the terminology for health-enhancing food products applies to both functional food and nutraceuticals/supplements (Hobbs et al. 2014a).

Differences in terminology raise costs and create uncertainty for firms marketing across international borders and, as such, can hinder the expansion of international trade in these products. Certainly, a firm contemplating developing export markets for a functional food or supplement/nutraceutical needs to be fully cognizant of the food category in which its product will be defined and the specific regulatory approvals required for marketing the product with a health claim.

In establishing regulatory frameworks governing the health foods sector, policymakers face the challenge of striking an appropriate balance between the protection of consumers from false and misleading claims that weaken consumer confidence in the sector and facilitating research and development (R&D) leading to new health foods product innovations. Regulation in this sense is a delicate balancing act. Regulatory

frameworks governing the use of health claims and the approval of new products with novel traits protect consumers; however, slow and restrictive approval processes and inadequate protection of intellectual property rights may weaken incentives to innovate and restrict the availability to consumers of potentially health-enhancing food products (Hobbs et al. 2014b). Among ostensibly broadly similar, well-established, developed markets examined in this entry, significant differences in regulatory approaches still exist.

The USA and Canadian markets for health foods products, for example, have a number of similarities, yet the Canadian regulatory system has been criticized for being slow to adapt to the changing nature of technology in the sector. Most of the disease-risk reduction claims currently permitted in Canada have been available to firms in the USA for a much longer time period, and the list of permissible health claims in the USA is more extensive than in Canada. Given the relatively small size of the Canadian domestic market, firms may be deterred from seeking regulatory approval for a new health claim if this is an overly slow and costly procedure compared to the potential payback of targeting a larger market such as the USA (Hobbs et al. 2014a).

Another example of regulatory difference is the use of “qualified” health claims supported by less rigorous scientific evidence in the USA and Japan. The authorization of qualified health claims requires lower standards of evidence and usually requires the provision of a disclosure statement or less authoritative wording. This stands in stark contrast to the EU, Canada, and other countries such as Australia and New Zealand, which reject the use of lower standards for disease reduction claims because of the risk of misleading consumers.

Another notable difference in the approach to health claims across countries is the treatment of product-specific health claims. Generic claims create a potential free rider problem: many firms benefit but only one firm has to go through the application process to obtain approval for a new health claim. Japan allows product-specific health claims for functional food, as does Canada for NHPs. Nevertheless, the generic health claim

systems in use for food in the USA, Canada, and the EU have the advantage that more products can use approved health claims with the potential to facilitate improved consumer knowledge of the relationship between diet and health.

Some countries do not make a regulatory distinction between supplements and (functional) food (e.g., Japan), although this is relatively rare. In many other countries, the two categories are distinct from a regulatory perspective, as is the case in Canada, where NHPs face a product-specific regulatory system but functional foods utilize generic health claims, and elsewhere, such as in Australia and New Zealand, where a functional food is subject to a harmonized regulatory system across the two countries, unlike supplements which are subject to separate national regulatory treatment. While the USA makes a distinction between food and dietary supplements, it does not impose significantly different regulations (the same generic claims are available to both product categories). The EU treats food supplements as a “food” but restricts the definition of food supplements to vitamins and minerals.

Choosing between making a generic or product-specific claim is also a strategic dilemma facing firms. If a generic claim is made, then the regulation is usually less stringent, depending on the product category, but the claim does not belong to that firm on that product alone. If the firm instead registers a product-specific claim (with potential monopoly rents), the product must meet more stringent approval processes. Ultimately, a firm’s decision will depend on the firm’s strategic assessment of these trade-offs, as well as the perceived level of uncertainty in the health claims approval process for a particular market (Hobbs et al. 2014a).

Charting a path through this complex array of regulatory approaches can be a bureaucratic headache for firms targeting international markets; they must determine which set of regulations apply to their products and the extent to which the same product will receive different regulatory treatment in different markets (Hobbs et al. 2014a). Divergent regulatory requirements with respect to what constitutes an allowable health

claim on a particular product raise the costs of accessing international markets and become an unintended consequence of regulation.

Replaceability Argument in the Ethics of Animal Husbandry

Nicolas Delon

Department of Environmental Studies, New York University, New York, NY, USA

[Conscientious omnivorism](#); [Happy meat](#); [Sustainable meat production](#)

Introduction

Most people agree that inflicting unnecessary suffering upon animals is wrong. Many fewer people, including among ethicists, agree that painlessly killing animals is necessarily wrong. The most commonly cited reason is that death (without pain, fear, distress) is not bad for them in a way that matters morally or not as significantly as it does for persons, who are self-conscious, make long-term plans, and have preferences about their own future. Animals, at least those that are not persons, lack a morally significant interest in continuing to live. At the same time, some argue that existence itself can be good, insofar as one's life is worth living. For animals, a good life can offset a quick, if early, death. So, it seems to follow that breeding happy animals that will be (prematurely) killed can be a good thing overall. Insofar as slaughter and sale makes it economically

sustainable to raise new ones, who would otherwise not exist, raising and killing animals for food who will have lives worth living is good overall. It benefits them as well as consumers and makes the world better by adding to the sum of happiness. The process of raising and killing animals with positive welfare produces a sequence of replacement that maintains or increases overall welfare, all else being equal (assuming in particular no overall negative impact on the welfare of other parties). Call this the *replaceability argument* (RA) and the ensuing controversy the *replaceability problem* (RP). This is a problem at the crossroads of the ethics of killing, agricultural ethics, procreation ethics, and population ethics. Peter Singer gave the idea its most precise and controversial formulation in *Practical Ethics* (2011: Chapter 5), first published in 1979.

History of the Problem

In 1789, in the *Introduction to the Principles of Morals and Legislation*, Bentham (1907) wrote:

If the being eaten were all, there is very good reason why we should be suffered to eat such of them [animals] as we like to eat: we are the better for it, and they are never the worse. They have none of those long-protracted anticipations of future misery which we have. The death they suffer in our hands commonly is, and always may be, a speedier, and by that means a less painful one, than that which would await them in the inevitable course of nature... [W]e should be the worse for their living, and they are never the worse for being dead. But is there any reason why we should be suffered to torment them? Not any that I can see. Are there any why we should *not* be suffered to torment them? Yes, several.

Bentham went on to formulate his oft-quoted criterion for equal consideration:

It may come one day to be recognized, that the number of the legs, the villosity of the skin, or the termination of the *os sacrum*, are reasons equally insufficient for abandoning a sensitive being to the same fate. What else is it that should trace the insuperable line? ... the question is not, Can they *reason*? nor, Can they *talk*? but, Can they *suffer*? (Bentham 1907: XVII.1)

Bentham, the founder of classical utilitarianism, appears to endorse a version of RA:

painlessly killing animals makes everyone better off than they would otherwise be – it does not harm them – meat eaters are better for it. Given the more sophisticated cognition of mature human beings, killing them requires stronger justifications, although Bentham believed the main reason against murder lied in the terror (foreclosed to animals) it would induce in *other* people.

Early animal rights advocate Henry Salt, despite Bentham's influence, called RA "the logic of the larder" (1914). Salt was responding to the essayist Leslie Stephen's (1896) argument against vegetarianism:

Of all the arguments for Vegetarianism none is so weak as the argument from humanity. The pig has a stronger interest than anyone in the demand for bacon. If all the world were Jewish, there would be no pigs at all.

Salt took Stephen's remark to be premised on a fallacy:

It is often said, as an excuse for the slaughter of animals, that it is better for them to live and to be butchered than not to live at all. Now, obviously, if such reasoning justifies the practice of flesh-eating, it must equally justify *all* breeding of animals for profit or pastime, when their life is a fairly happy one. . . . In fact . . . there is hardly any treatment that cannot be justified by the supposed terms of such a contract. Also, the argument must apply to mankind. . . . The fallacy lies in the confusion of thought which attempts to compare existence with non-existence. A person who is already in existence may feel that he would rather have lived than not, but he must first have the *terra firma* of existence to argue from; the moment he begins to argue as if from the abyss of the non-existent, he talks nonsense, by predicating good or evil, happiness or unhappiness, of that of which we can predicate nothing. (Salt 1914: 221–222)

Peter Singer, in the first edition of *Animal Liberation* (1975: Chapter 6), agreed with Salt. He changed his view while writing *Practical Ethics* (first published in 1979, revised in 1993 and 2011), influenced by ingenious arguments put forward in the late 1970s by Derek Parfit about impersonal wrongs and the widely discussed "nonidentity problem" (1984: 351–374). Based on the fictional case of two prospective mothers and medical programs (367), Parfit showed that one could act wrongly without harming anyone in particular.

Despite a plausible asymmetry between harms and benefits, and the fact that parents are under no *obligation* to bring to life a child whose existence will very likely be happy, one needs to explain why it is wrong to bring a miserable being into existence (even one who would otherwise not exist) yet not equally good to bring a happy being into existence. "Sound explanations for this," Singer and Mason wrote, "are extraordinarily difficult to find" (2006: 252). It may be at most "morally neutral" (optional), but it is at least good.

Structure of the Argument

In its basic form, RA states that one can increase or maximize value in the world (happiness, pleasure, preference satisfaction, objective list) by increasing the number of happy or fulfilled sentient beings. Applied to farming, it states that humanely raised animals (HRAs) that live pleasant lives and can be killed without pain and distress can be replaced, without loss, by new HRAs, which thus offset the good prevented by the killing. Humanely raising and killing animals benefits animals, consumers, and the world.

There are two ways to interpret the offsetting of an early death by a good life: either animals are *personally* better off with a happy, if short life, than with no life at all or, even if the personal harm of death is not offset by the benefit of existence, the *impersonal* marginal benefit "for the world" offsets the total sum of personal harms. Each interpretation requires different arguments: either to the effect that death does not significantly harm animals (so the net sum of personal benefits minus harms for the individual is positive) or that impersonal benefits may override personal harms (so the overall sum of benefits minus harms, for all affected, is positive). Either way, one has to show that the total benefits of eating meat outweigh the costs to animals (McMahan 2008).

Contemporary Applications

In the context of intensified industrialized farming, critiques and alternative methods have

flourished. A popular trend in animal husbandry, espoused by food writers, celebrity farmers, and academics, focuses on the possibility of eating better *and* treating animals better – in part by eating fewer of them. “Conscientious,” “ethical,” or “compassionate” omnivores embrace the humane, pasture-based, grass-fed, and, often-times, organic and local production of meat as a sustainable solution in the ailments of the modern Western diet. Humane husbandry and a conscientious omnivore diet minimize environmental damage, animal suffering, and public health issues while preserving a (culturally, aesthetically, and economically) worthwhile practice. Animals, in exchange for life and care, offer us their own life. Ethically produced meat ideally comes from free-ranging animals who enjoyed (slightly) extended life spans (allowing animals to live their expected natural life span would dramatically increase market prices), increased outdoor access, environmental enrichment, a more natural diet (grass, organic cereals, fruits, vegetables, roots), and social relations. Contemporary practitioners and/or advocates include Hugh Fearnley-Whittingstall (2004), Nicolette Niman, Joel Salatin (Polyface Farms), Michael Pollan (2006), and Allan Savory, among others.

There is another purported benefit of husbandry to animals. Its end would not only deprive billions of future *individuals* of a good life, it would ultimately mean phasing out entire domesticated *species* and *breeds*. Thus, Pollan writes, chickens “depend for their well-being on the existence of their human predators. Not the individual chicken, perhaps, but Chicken – the species. The surest way to achieve the extinction of the species would be to grant chickens a right to life.” (2006: 322). This is assuming, controversially, that limited populations of such breeds or species would not thrive in the wild or sanctuaries. This is also suggesting, again controversially, that these kinds have intrinsic value and lack wild counterparts. Moreover, RA only applies to those individuals and kinds that would not exist otherwise, hence, for instance, not to wild-caught fish or independently reproducing game. Finally, any given type of agriculture will affect the number, species, and well-being of the animals that will exist on the

land used or converted (Matheny and Chan 2005). There is also a widespread assumption that domestication is an advantageous bargain for animals, insofar as husbandry provides for their needs, food, shelter, veterinary care, and protection against predators and diseases and ensures the reproductive success of the population (Budiansky 1999; Pollan 2006), but as section “[Philosophical Controversy](#)” shows, such comparisons involve complicated metaphysical questions.

In the actual world, RA strikes more directly at veganism than ovo-lacto-vegetarianism, since producing dairy, eggs, and other animal by-products cannot be dissociated from killing, in part because the profitability of livestock depends on the marketability of by-products and because male calves and chicks and spent females are not useful to the industry. Critics, on the other hand, point out that, even granting its validity, the logic of the larder does not entail that such practices will be morally acceptable. RA entails, at best, that one *could* hypothetically have reasons to eat animals – with meat probably becoming a luxury good (McMahan 2008). But further obstacles stand in the way of even heirloom husbandry: the unreliability of labels; inevitability of slaughterhouses for animals raised for commercial purposes; limitations of mobile slaughter units and gruesomeness of “backyard butchers” (McWilliams 2015); reduced life spans; mother-offspring separation; castration, clipping, docking, and other mutilations; increased mortality and morbidity rates; and environmental concerns (waste, GHG emissions, land and water use), let alone empirical and ethical uncertainties regarding the badness of death for real and hypothetical HRAs (Višak and Garner 2016). Singer and Mason (2006) note: “[humanely raised] cattle, like all the animals we eat, died while still very young. They might have lived several more years before meeting one of these other forms of death, years in which they matured, experienced sexual intercourse, and, if they were females, cared for their children” (253). Therefore, even without granting animals a right to life, RA does not settle by itself the permissibility of the current humane omnivore diet.

Philosophical Controversy

Philosophers accepting RA (e.g., Hare 1999; Scruton 2004; Singer 2011; Varner 2012) assume at least a version of these two claims: death is not a significant harm to nonperson animals; existence is better than nonexistence (for HRAs, other sentient beings, and/or from the point of view of the universe). Singer and Varner also accept that these may be matters of degree.

Hare, Singer's mentor at Oxford, considered Stephen's comparison very sensible: "happy existing people are certainly glad they exist, and so are presumably comparing their existence with a possible non-existence" (1999: 239). If he were to choose between the life of a trout in a small farm in the English countryside and never existing, Hare would certainly "prefer the life, all told, of such a fish, to that of almost any fish in the wild, and to non-existence" (240).

Singer (2011: Chapter 5) now accepts that a good if short life is better than nonexistence. Sentient life even has a preference-independent (objective) value, such that more good lives are better than either a less happy or a non-sentient universe. These claims are even easier for Singer to accept now that he espouses *hedonistic* act-utilitarianism (Lazari-Radek and Singer 2014): the permissibility of a given act of killing depends on the overall resulting balance of enjoyment and suffering. On this view, persons are also replaceable, although, given the richness of their lives and the numerous side effects, not as easily as merely sentient beings (also see Varner 2012).

Distinctions

At the crux of RP stand unresolved questions in moral theory, applied ethics, and axiology (Višak and Garner 2016): When is death a harm? What is the relevant point of comparison to assess (momentary or lifetime) welfare? How does a short happy life compare with nonexistence, life in the wild, or a longer life? Each comparison has its own complications, including nonidentity problems between wild and domesticated animals, different generations, and different life stages of individuals.

The theoretical application of RA to nonperson animals, but not to persons (self-conscious, rational, and autonomous), hinges on the assumption that death is normally distinctively bad for the latter if their lives are worth living. Death can be a tragedy only for persons. RA thus rests on two central distinctions: *suffering* versus *death* and *persons* versus *nonpersons*, which may explain why many people opposing animal suffering do not necessarily oppose the killing of animals for food, and why people who would consider killing human beings, including anencephalic children, for horrific medical research generally accept experimenting on at least as sentient nonhumans. Non-speciesists substitute persons/nonpersons for humans/nonhumans, since some nonhumans can be persons (e.g., great apes and cetaceans) and not all humans are persons (e.g., fetuses and anencephalic children). Even a non-speciesist can therefore deny that the death of a cow and the death of a *normal* human being are on a par, given their different cognitive capacities (Bentham 1907; Singer 2011; Varner 2012).

Metaphysical Issues

Utilitarian versions of RA depend on the crucial assumption that the interests of nonexisting beings matter – not simply those of beings that do exist or will exist (regardless of one's choices) but also those of beings who *would* exist *if* one chose to bring them into existence (i.e., whose existence and identity depend on one's choices). The question is whether the interests of already conceived future children matter like those of *merely possible* children. If interests count only once one has determined that a being will exist, it is problematic to balance the interests of possible farm animals against their interests if they exist. Critics of RA say one ought to ensure existing animals are made as happy as possible when they are alive but ought not to make as many happy beings as possible (Višak 2013).

RA proponents can press that acknowledging that existence can be good implies that existence can be *better* than nonexistence (benefit) and hence that nonexistence can be worse (harm). RA opponents insist that nonexisting beings have no welfare so there is no one for whom

existing is better than never existing. Existence, on this view, is an *absolute*, i.e., non-comparative, benefit. Secondly, accepting that *existing* beings can prefer their existence to nonexistence does not commit one to accept that *merely possible* beings would prefer a short happy life to no life at all. In fact, preferring existence to never existing may as well count *against* killing (no longer existing). It is an open question whether absolute benefits can compensate for harms such as death, but it is plausible that happy animals, if they were in a position to assess such benefits and harms, would prefer life to death. They would, moreover, not be swayed by the fact that, had one not planned to kill them, they would not exist, since existence is not a comparative benefit.

Utilitarianism

Hare (1999: 239–239) makes a clear utilitarian case for replaceability:

doing wrong to animals must involve harming them. If there is no harm, there is no wrong. Further, it has to be harm overall; if a course of action involves some harms but greater benefits, and there is no alternative with a greater balance of good over harm, it will not be wrong. We have to ask, therefore, whether the entire process of raising animals and then killing them to eat causes them more harm overall than benefit. My answer is that, assuming, as we must assume if we are to keep the “killing” argument distinct from the “suffering” argument, that they are happy while they live, it does not. For it is better for an animal to have a happy life, even if it is a short one, than no life at all.

Although, existence is not “a benefit in itself,” “it is a necessary condition for having the benefits that we can have only if we are alive” (239). Existence can be compared (and preferred) to nonexistence and existence allows for more preferences to be satisfied. Hare endorses *total* (as opposed to average and person-affecting) *utilitarianism* – i.e., we ought to “maximize the total amount of preference-satisfaction that is had in the world ... and distribute it impartially.” Painlessly killing animals, as opposed to making them suffer, does not frustrate their preferences. Assuming there are no uncompensated negative side effects, the permissibility of killing thus depends on “how many live animals, of different species including the human, we ought to cause

there to be” or, more accurately, the number of quality-adjusted life years (QALYs) (239). Hare concludes that traditional “organic” husbandry (replaceability), especially in parts of the world where growing crops is impractical, is *optimific*. Note that Hare’s argument is stronger than Singer’s theoretical endorsement of replaceability. It states not only that replacing animals is permissible, but that it is *required* when *optimific*. Lazari-Radek and Singer (2014) have recently come closer to such a view (hedonism aside).

As is clear, RA follows naturally from certain versions of utilitarianism. In fact, Pollan’s (2006) defense of meat, besides its empirical and axiological assumptions (predation as symbiosis; species matter more than individuals), echoes utilitarian commitments (Singer and Mason 2006: 252). Replaceability is, indeed, a crucial ground for deontological and rights-based objections to utilitarianism, insofar as the latter sees individuals as replaceable “*receptacles of value*” (pleasurable experiences) (Regan 1983). Yet, while RA squares well with utilitarianism, rejecting its conclusion need not entail rejecting utilitarianism.

Further distinctions are necessary here. There are personal and impersonal values, which can be ranked differently. A state of affair can be impersonally good independently of its goodness-for-particular beings, from what Sidgwick called “the point of view of the universe.” The existence of more happy animals might be impersonally better even if it were better for no one in particular. On the other hand, states of affairs can be personally better or worse for those existing in such states. Happy/long lives are better for cows than short/miserable lives. So, a state of affairs could be personally worse than its alternatives while being impersonally better: e.g., replaceability is worse for cows, who live shorter lives than they could and are not better off for existing, but the world is better in virtue of containing more happiness than a world of irreplaceable cows.

On *total impersonal* utilitarianism, impartiality requires that one weighs the interests of actual (present and future) beings and possible beings equally, in proportion to their strength rather than

whose interests they are. But several authors emphasize the compatibility of prior-existence/person-affecting utilitarianism (let alone rule consequentialism) with the irreplaceability of persons or of all sentient beings. They assume, as mentioned earlier, that nonexistent animals have no welfare, so they cannot be harmed or benefitted by existence or nonexistence. The interests of possible beings thus do not matter as much, if at all, as those of actual beings (Sapontzis 1987; Višak 2013; cf. Parfit's 1984 and Singer's 2011 [1979, 1993] discussion). These views thus reject a central tenet of RA.

Both person-affecting and impersonal views may have bullets to bite. The former are hard-pressed to account for the intrinsic wrongness of breeding animals that will undergo lives of suffering, if one cannot be harmed by being brought into existence. Of course, once one exists, it is wrong to be made to suffer. But one lacks *direct* reasons, on the person-affecting view, to avoid breeding animals that will have miserable lives as a result of genetic defects or induced disabilities. *Wide-person-affecting* views, however, offer interesting resources (Višak 2013). On the other hand, purely impersonal views cannot easily account for the intrinsic wrongness of killing and involve comparisons between states of affairs that are not straightforwardly meaningful from the point of view of those they affect. They can accept that not breeding conscious animals has neutral (neither positive nor negative) value. But they cannot make a difference between the good that is achieved by prolonging an existing being's life and creating beings that would not otherwise have existed. Moreover, *hedonistic* impersonal utilitarians lack resources to account for the distinctive wrongness of killing persons except in terms of their side effects on other parties and the relative richness of their future lives, all of which can be compensated for on such views. Singer's changing views over the editions of *Practical Ethics* are representative of these difficulties. His recent shift from preference utilitarianism to hedonism deprives him of his previous arguments for the irreplaceability of persons.

To conclude, RP thus leaves us with the theoretical challenge of providing a compelling case

for the replaceability of nonpersons that does not apply to persons. Most authors either accept replaceability for *both* persons and nonpersons (Lazari-Radek and Singer 2014; Varner 2012) or deny it for both (Višak 2013). Further, practically, RP does not settle all of the morally relevant aspects of animal husbandry. The best defense of conscientious omnivores rests on several empirical and philosophical assumptions still being hotly debated (McWilliams 2015; Višak and Garner 2016).

Conclusion

Controversies regarding the ethics of animal husbandry and eating meat sometimes revolve around the idea of replaceability, namely, that killing certain animals can be permissible insofar as they live pleasant lives and are replaced by new animals with equally pleasant lives. The controversies touch upon foundational issues in moral theory, practical ethics, as well as contemporary discussions of "ethical," "conscientious," or "humane" omnivores.

Introduction

Resource conflict refers to tensions, disagreements, disputes, and struggles involving control over, or use of, land, water, forest, pasture, and related environmental features. Wars, violence, and insecurity related to resources, ranging from the oil fields of Iraq, the savannas of Darfur, the

jungles of Chiapas, and the rural-urban interface of China. What constitutes a resource seems straightforward: an element of nature that people value and seek to use to attain an end. Defining value and use, however, is always culturally mediated, so that different societies may hold very different meanings, needs, and priorities regarding the world they inhabit. Despite the global spread of commercialization, Elizabeth Emma Ferry and Mandana Limbert (2008, p. 4) point out that "... nothing is essentially or self-evidently a resource. Resource-making is a social and political process, and resources are concepts as much as objects or substances." The presence of different cultural views and practices about the environment might not be recognized or easily translated, so that this incommensurability of understanding may in itself become a source of conflict.

The language of conflict, including of its resolution or transformation, is notoriously imprecise. For present purposes, "conflict" is defined broadly here as a situation where people clash due to a perceived serious incompatibility in their needs and interests, making the status quo no longer acceptable. This definition draws attention to the importance of focusing on underlying concerns and motives, rather than on outward manifestations of discord or antagonism. When dealing with food and agriculture, many conflicts are latent, reflecting structural inequalities, differences of power, or similar social cleavages. These latent conflicts are often deeply rooted in historical political economies and cultural institutions. Similarly, seemingly local or small-scale disputes may have broader socioeconomic, political, or cultural conflicts embedded in them. In general, the form and intensity of resource conflict vary widely. Conflict occurs at all societal levels, from the intra-household to the global. In many places resource conflicts appear to be increasing, driven not only by rising demand but also by political, socioeconomic, and cultural change. While humanity possesses the capacity to address issues of injustice and competitive consumption that drive many of these conflicts, it is by no means certain that it will be able to do so.

The Questions of Causality and Understanding

Resource conflicts abound, and so do explanations for them: structural inequalities rooted in historical political economy, environmental scarcity, need or greed, resource curses, bad governance, and so on. To a large extent, these different interpretations reflect the varying theoretical interests and assumptions of their proponents. For example, Thomas Homer-Dixon's (1994) neo-Malthusian analysis highlights the role of population growth and rising consumption pressures as key factors in sparking violent environmental conflicts. In contrast, Nancy Lee Peluso and Michael Watts' (2001) collection of political ecology case studies focuses on how violence is a social project shaped by the imperatives of state power and market-driven actors in specific settings. These differences in approach also underscore the wide range, complexity, and dynamism of conflicts, making it impossible to understand them fully from a single analytical framework. Resource scarcity, competition, inequality, poverty, neoliberalism, neocolonialism, and so on may seem as if they are "obvious" causal or triggering agents for conflict, yet people may decide to respond to circumstances through peaceful, rather than conflict, pathways. The plausibility of singular prime movers or triggers declines when one moves from the macro level to particular cases, where site- and actor-specific variables become more visible. This is not to say that inequalities, scarcity, governance, and so on do not matter, but rather that their relevance and significance in any setting be demonstrated rather than stipulated.

Understanding resource conflicts means understanding people, their characteristics, capacities, interests, and priorities. This means recognizing human diversity, including differences of gender, age, cultural background, and other dimensions. Gender, which refers to the culturally defined roles, relationships, and responsibilities of females and males, is an especially significant variable. The importance of women as resource controller and users is often underestimated or downplayed, which in itself has been a source of

conflict. Discrimination against women embedded in tenure systems defined by custom, religion, or state authority is an inherent source of tension, given on-the-ground realities of women's actions as resource decision-makers and users. It is important to bear in mind, however, that conflict can follow "myriad social fault lines, pitting national and local elites against ordinary citizens, neighbor against neighbor, kinsmen against kinsmen, and husbands against wives" (Berry 2002, p. 639). In a study of land conflicts in pre-genocide Rwanda, for example, Catherine André and Jean-Philippe Platteau (1998) found that intense competition for resources spurred by population pressures, increasing inequalities, and changes in inheritance custom had brought property disputes into "the very heart of family life" as children clashed with parents and siblings with each other.

Egalitarianism and Its Legacy

Unequal access to resources is one of the major factors generating conflict at all societal levels. It is a pervasive feature of today's globalized existence, as well as for many societies in the past. In fact, the legacy of past structural inequalities still influences the occurrence and character of resource conflicts in several parts of the world. For most of human history, however, food procurement occurred in a very different setting: small-scale, egalitarian foraging societies. The legacy of this long period of humanity's past is worth considering. Christopher Boehm (2012) observes, since it is the period when humanity's sense of morality emerged as a part biological and cultural evolution. His account of forager society differs from the Hobbesian portrayal of a realm where everyone was the enemy of the other. Drawing on ethnographic and other evidence, Boehm argues that sharing and cooperation in hunting, food distribution, and other tasks served as the cauldron for the rise of a moral community. Boehm also contends that egalitarianism was not the inevitable outcome of food or other material limitations among foragers but an outcome of an "intentionally reverse dominance order." Peer pressure and sanctions held in check those

deemed as too self-serving and disruptive. Douglas Fry (2006) has observed that foraging bands most frequently dealt with resource scarcity by sharing, rather than with hostile competition, expecting reciprocity at a future time. Crosscutting ties based on kinship, friendship, shared rituals, and trade fostered trust and cooperation.

Sharing and reciprocity continue to be major economic principles in contemporary foraging societies, as well as among family-based farmers and herders, along with the urban poor. For people with low incomes, mutual assistance from relatives, friends, and neighbors constitutes a key economic resource, helping to overcome shortfalls in money, food, labor, and other needs. The reliance on cooperation does not mean that intra- or intergroup resource competition or conflict is not present. As in all places, at all times, conflict happens. Its occurrence may serve to jeopardize these networks of assistance. People recognize their importance, taking care to maintain social ties, striving to mend them when breakdowns occur. Leading procedures of conflict resolution – negotiation, mediation, adjudication, and reconciliation – also arose during humanity's long history as foragers. A significant body of literature on conflict management and peacebuilding for resource conflicts and land disputes has emerged, including policy- and training-oriented works emphasizing collaborative approaches (Castro and Nielsen 2003; Castro and Engel 2007).

The Rise of Structural Inequalities

Despite these measures, societies eventually arose in human history characterized by what Jean-Jacques Rousseau called in 1754 moral or political inequality, organized on the basis of "different privileges enjoyed by some at the expense of others" (1987, p. 38). The emergence of hierarchical societies based on differential access to power and productive resources is recent by human evolutionary terms, first appearing only a few thousand years ago. With great insight, Rousseau attributed political inequality to the rise of agriculture and the gradual emergence of new

ideas and practices regarding property. People came to accept privileged access to land, which altered in a fundamental way their relationships to each other:

The first person who, having enclosed a plot of land, took it into his head to say *this is mine* and found people simple enough to believe him was the true founder of civil society. What crimes, wars, murders, what miseries and horrors would the human race have been spared, had someone pulled up the stakes or filled in the ditch and cried out to his fellow men: 'Do not listen to this imposter. You are lost if you forget that the fruits of the earth belong to all and the earth to no one!' (Emphasis in the original; Rousseau 1987, p. 60)

Agrarian states, such as in Europe and Asia during Rousseau's lifetime, were characterized by deep social inequalities. Disempowered rural populations had been converted into serfs, slaves, and tribute-paying peasants. As John Bodley (2001) observes, hierarchical societies by their very nature are predatory, always seeking to expand their access to resources, while experiencing competition from within for control over assets and the benefits from them.

The rise of the industrial capitalism based on global trade, wage labor, and technology run by fossil fuels extended and intensified inequalities. Resource conflicts were rife as enclosure movements, market pressures, and political actions promoted greater commercialization of property and rural labor arrangements. Colonial regimes in the Americas, Asia, and eventually Africa used violence and treaties to dominate and displace local populations. Estates, plantations, mines, forest reserves, and other commercial enclaves appeared, while colonial policies sought to convert local populations into cheap labor reserves to meet the needs of these new enterprises. Small farmers, herders, and foragers frequently found themselves in a precarious existence, their tenure rights insecure or unacknowledged, and with market and political processes favoring haves over have-nots. Political independence by itself failed to alter the circumstances of rural populations in the former colonies. The new leaders, like their predecessors, generally felt that indigenous or local resource institutions lacked development potential.

Agrarian inequality has generated conflict throughout history. On a daily basis, however, these tensions have been usually latent rather than open in character. For various motives, including feeling vulnerable to reprisals, people have avoided demonstrating dissatisfaction. "Agrarian peace," noted James Scott (1985, p. 40), may be "the peace of repression (remembered and/or anticipated) rather than the peace of consent or complicity." Scott coined the phrase "weapons of the weak" to describe covert acts of resistance by oppressed groups. Resistance could take the form of theft, false compliance, sabotage, or other acts interpreted as criminal rather than political by those in power. Sometimes rural grievances erupted into rebellions and revolts. Karl Marx and Fredrick Engels predicted that capitalism's inequalities would provoke revolutions in industrial societies, but these upheavals mainly occurred in agrarian nations. Conflicts over land, resources, and political rights triggered revolutionary struggles in Mexico, Russia, China, and elsewhere. In some countries significant reforms occurred such as land redistribution and greater investment in rural public services. But these measures inserted new forms of state control vis-à-vis the rural population through land nationalization, collectivization, market controls, or other actions. New vulnerabilities and grievances arose among rural dwellers. Maoist China offered one of the most deadly examples, where perhaps 30 million people died of hunger during its Great Leap Forward program of the late 1950s. Market-based reforms since the late 1970s removed many of these "revolutionary" policies, opening new economic opportunities, but also setting launching new scrambles for resources.

Resource Conflicts in a Globalized World

Market reforms embraced by most of the world's governments in recent decades have aimed to promote economic growth as the solution to humanity's problems. Economic globalization has accelerated resource extraction to meet rapidly, if unevenly, expanding demand worldwide while simultaneously promoting deterritorialization,

reducing the role of political boundaries in separating humanity. As Jack Weatherford (1997, p. 7) points out, "we now are united in one network, in a single grid of interlocking institutions that spans the globe... The same market connects every country, every language, and every religious and ethnic group." While money allows these social relationships to appear transitory, their connections and consequences still exist. Seemingly trivial decisions made by individuals connect them with people elsewhere who may suffer great harm. For example, rising consumption of processed foods has greatly increased demand for palm oil among manufacturers. Consumers are usually unaware of its presence in their snacks and meals. Food processors find this saturated fat a useful ingredient. One of its main attractions is its low cost to them, which they obtain from Indonesia and other tropical countries. Rising palm oil demand has resulted in the expansion of plantations, displacing many communities and destroying rain forests. Globalization has helped to some extent the critics of the palm oil industry, facilitating their ability to transmit information about this situation. It is an uneven contest, at least for now, as palm oil consumption continues at a brisk pace.

Multinational businesses increasingly exercise influence over the allocation of agricultural and food-related resources globally. According to Raj Patel (2007, pp. 99–100), "Today, transnational agricultural corporations control 40 percent of world trade in food, with twenty companies controlling the world coffee trade, six controlling 70 percent of wheat trade, and one controlling 98 percent of packaged tea." Corporate involvement in food and related sectors has been touted as a way of promoting efficiency and innovation, promoting application of the latest industrial and biotechnology innovations. Agribusiness itself, however, is a source of conflict. Critics have long charged that corporations have used their market power and political connections to squeeze profits from both farmers and consumers. The health and environmental impacts of industrial agriculture have been other sources of controversy; for example, consequences arising from farm chemicals, feedlot wastes, and factory pollution. Agroecological studies carried out by Jules

Pretty (2005) and others document industrial agriculture's externalities – enormous financial costs absorbed by society and ecosystems as a subsidy to business. These costs include numerous and widespread damage to human health; declining quality of water, soil, and air; and reduced wildlife and overall biodiversity. Nevertheless, the political and market clout of industrial agribusiness interests are so powerful that such concerns are not easily addressed in civic society.

The scope and magnitude of conflicts related to corporate investment in agriculture and related sectors is likely to increase in the future, reflecting its current boom occurring worldwide. The so-called global land grab emerged in the news media during 2008, in the midst of rising food prices and collapsing financial markets. It had been already under way for years, stimulated by deregulation, privatization, food security concerns, China's economic rise, and promotion of "green" businesses such as biofuels and carbon forestry. Investors have targeted agriculture and resource sectors on all continents. An early report by GRAIN (2012), a nongovernmental organization, identified investments as coming heavily from China, India, and the Gulf States, as well as the West. The types of investors also attracted notice, as they included not only the expected agribusiness firms but also hedge funds, financial service organizations, and sovereign wealth funds. Governments, especially in developing countries, often sought out investors as a means of promoting economic development through capital and technology transfers. Officials leased or sold areas, usually without consulting the communities that depend on such areas for their livelihoods. Public information is generally lacking about these deals. No one knows how much land has been transferred to investors. The Land Matrix Project verified the existence of 924 agreements in the Global South and Eastern Europe involving 200 ha or more through September 2011. These agreements involved 48 million hectares, with 35% of this land located in Africa. Many deals have yet to be verified.

The land agreements pose a major threat to the livelihoods and lives of communities, generating conflict. According to Human Rights Watch

(2012), more than 70,000 people from Anuak and Nuer ethnic groups from Gambella, Ethiopia, are slated for involuntary resettlement so that Karuturi Global, an Indian agribusiness firm, can take over their land. They have sought redress in a number of settings, though without success to date. Their situation is by no means unique. On the contrary, development projects worldwide, including dams, roads, urbanization, mines, industrial complexes, and resorts displace an estimated 10 million people annually (Oliver-Smith 2005). In China alone, officials expropriated more than six million hectares of land for urban expansion between 1990 and 2010 (Amnesty International 2012). Aside from the trauma of the moves, these communities have had to struggle with issues of compensation, the process of moving, and the conditions of resettlement. Their experiences have often underscored their lack of bargaining power and inability to get governments, development agencies, and businesses to fulfill their obligations and responsibilities. Voluntary performance standards regarding human rights and environmental sustainability, such as the Equator Principles, have been adopted by development institutions and private businesses, but their effectiveness is not yet demonstrated. Communities have used lawsuit to pursue resource grievances, though they usually encounter substantial institutional, political, and other obstacles.

Global demand for resources has prompted modes of resource extraction that are less orderly than those found in land agreements and performance standards. Robert Buijtenhuijs (2000, p. 115) observed that in the 1980s, “a new phenomenon of ‘predatory war’ emerged in Africa... insurgent movements [who seek]... to secure by force of arms the economic resources in those areas which combatants control.” They have focused on control of petroleum and valuable minerals such as diamonds, gold, and coltan, but agriculture and food supplies are often severely impacted by violence and insecurity. The unchecked global spread of small arms has enhanced the lethal capacity of these wars. Many studies have identified a “resource curse,” which correlate to a rich natural resource

endowment with seemingly incongruent poverty and endemic conflict (Collier and Venables 2011). “Cursed” situations are not inherent but the outcome of interests internal and external to these countries that benefit from modes of resource extraction utilizing violence and insecurity.

In spite of the challenges posed by globalization to community-based resource users, it has made it possible for them and supporters to mobilize on a wider scale. The uprising by the Zapatista National Liberation Army (EZLN) in Chiapas, Mexico, an area of perennial resource, class, and ethnic conflicts in 1994, received a tremendous boost from information-technology savvy supporters. Instead of being a little-known agrarian struggle in a remote part of southern Mexico, news spread quickly and globally about the EZLN’s agenda, including its opposition to the newly adopted North American Free Trade Agreement. Their information network also raised the visibility of the Mexican army’s counterinsurgency campaign, causing it to halt on occasions. This situation contrasted with the government’s past heavy-handed actions. Analysts at the Rand Corporation bestowed a new term, *social netwar*, to convey the skillful use of information technology in the opening phases of the EZLN’s campaign. Globalization’s influence is also evident in social movements such as *La Vía Campesina*, which brings together peasant, small farmer, and rural labor groups from around the world into a single organization. The United Nations now has a Permanent Forum on Indigenous People. Numerous NGOs such as GRAIN, the Oakland Institute, and Oxfam now deal with a range of land- and resource-related issues. Issues of agrarian justice such as land reform, which disappeared from policy discourse with the rise of pro-business policies, are being raised again by activists and academics (Rosset et al. 2006).

Resource Scarcity

A recent report by the United Nations Environmental Program estimated that in the twentieth

century, "... extraction of construction materials grew by a factor of 34, ores and minerals by a factor of 27, fossil fuels by a factor of 12, and biomass by a factor of 3.6" (UNEP 2011, p. 11). Remarkably, the report noted that overall prices for resources fell by 30% during this same period. Patterns of resource supply have been dynamic, however, with newer sources of supply being sought, while greater efficiency is pursued. Skeptics of this seemingly endless horn of plenty have argued that ratios of energy returned for energy invested appear to be declining for key economic sectors, including food, petroleum, and mining (Hall and Day 2009). As mentioned earlier, the price of commodities ignores many costs, which end up absorbed by the public and the biological system they depend on. Human-driven global warming and its complex impacts underscore the dangers of continuing business "as is." Low-income rural communities constitute the most vulnerable populations to climate change, yet they are the ones least responsible for it (Castro et al. 2012).

With global population nearing seven billion and pressures for increased levels of consumption on the rise, the issues of scarcity and limits to growth within the context of current and future resource conflict. Thomas Malthus argued in 1798 that populations will procreate beyond the capacity of their habitat to support them. Their numbers tend to increase geometrically, while their food supply expands only arithmetically, with famine, poverty, and death the inevitable outcome of this imbalance. His ideas proved influential and controversial, coming in and out of favor. Neo-Malthusianism grew in the 1960s with the rise of environmentalism and fears about ongoing demographic growth in a world of finite resources. At a time when insurgencies raged in Third World countries, skepticism emerged about whether governments and markets could meet the challenge of uplifting the poor. The Paddocks (1967) claimed in *Famine 1975!* that today's "hungry nations" would be tomorrow's "starving nations." Garrett Hardin (1974) urged rich nations to adopt "lifeboat ethics," maintaining their security by eliminating immigration, foreign aid, and other actions to help the

world's poor, whose overpopulated lands were essentially sinking ships. When Ethiopia's famine shocked the world in the mid-1980s, Hardin (1985) recommended withholding relief, since it would only exacerbate the underlying problem of too many people. The "let them starve" approach did not gain the public's attention.

The United Nations Environmental Program (2011) expects resource scarcity to emerge in coming decades. Michael Klare (2002, p. 213) believes that intensifying global competition for vital commodities will result in greater tension and disputes: "... resource wars will become, in the years ahead, the most distinctive feature of the global security environment." He suggests that this scenario could be avoided through cooperation, especially by setting up "robust international institutions" dealing with vital resources. Similarly, Thayer Scudder (2010) sees declining living standards ahead, as humanity exceeds biophysical limits to growth. Once again, he warns that conflict and strife are likely unless cooperation and remedial action occur. Such predictions have been wrong before, but what will happen in the future remains to be seen.

Summary

Conflicting interests in resources is a ubiquitous part of social life. How people have responded to such situations has varied through time. Forager and other egalitarian societies often relied on sharing and cooperation. The rise of structural inequalities in agrarian and industrial civilizations fostered more contentious circumstances, generating violence and insecurity regarding resources on a national and global scale. Resource conflicts are a pervasive part of today's globalized world, driven by consumerism and population growth in the context of deep inequalities. Globalization also offers opportunities for empowerment of marginalized populations and the international and equitable management of conflicts. Whether such actions will occur is unclear, especially given current fears about future global competition over vital resources.

Corporate responsibility; Ethical evaluation; Food industry; Innovation and risk; Stakeholders

Introduction

Corporations carry the responsibility of ensuring their own profitability, the key to their survival. Yet they have widespread impacts on people that share the social space with them, people who are in turn instrumental to their profitability. The food sector, perhaps more than any other, brings into sharp focus the contradictions inherent in this setup. Food is a basic human need, critical for sustenance, health, and well-being. Innovation is at the heart of increasing yields, lowering production costs, and optimizing profit margins. Yet what if they come at the cost of lowered quality or safety of the food thus produced? Such dangers have led to increased awareness and a keener

knowledge of food and nutrition issues among consumers, which in turn has put public pressure for greater transparency and accountability from the food sector.

Lawmakers have recognized the need to intervene, including, for instance, enforcing better labeling of ingredients and nutritional facts on food packaging. Corporations have been legislated or pressured to minimize or eliminate ingredients known to be harmful. However, the listing of components and percentages of various types of nutrition in a specific food product does not bring out information pertaining to practices used in producing, processing, or preserving food products. And some innovations will always be ahead of existing labeling requirements or known health risks. Are food corporations alone responsible to manage innovations whose results end up being ingested by millions of consumers? How could the food innovation process be better shepherded through to final regulatory approval? What if the innovation process were more fully integrated into the matrix of societal values from the outset of the design process? That notion is at the heart of Value Sensitive Design.

This entry aims to identify the stakeholders influencing the food industry and present the role and responsibility of each actor in working toward the common objective of growing and producing food that is both safe and healthy. Innovation in the food sector opens the way for corporations to harness the cutting edge of technology. In this context, Value Sensitive Design is an approach which seeks to better address uncertainty and ethical issues at an earlier stage in the life cycle of innovative food production so as to increase the probability that technological applications have a positive impact on health and safety.

Stakeholders Involved

The food industry consists of companies and corporations that are directly involved in the production, processing, preservation, distribution, presentation, and sale of food. The methods adopted and the courses of action taken determine

the nutritional value, quality, and long-term safety of food. Entities that play indirect roles may include research organizations, public agencies, and decision-makers, along with media that reflect societal values surrounding food and eating-related behaviors.

Research organizations include universities and other public agencies or private organizations that partake in innovation through experiment, analysis, and design. They naturally focus their research on the objectives of the parties that fund their efforts. Studies funded by industry tend to be geared toward profitability, taking less account of the wider value matrix through which the resulting innovations eventually ripple. The objectives of such studies may not include the fullest possible evaluation of health and safety. The testing done to identify harmful effects of cutting-edge food technology is often difficult to implement or non-exhaustive, due, for instance, to the presence of unexpected molecules or new biochemical combinations and the practical limitations of experimenting the synergistic or cumulative effect of each new element using methods based on previous food technology.

Public decision-makers and lawmakers are often influenced by the food sector toward approving industry practices even as they rely on the analysis and recommendations made by policy organizations for ensuring the health and welfare of consumers. Government agencies can protect the best interests of the latter by promoting responsible practices in the food industry. However, the current practices by which food products are certified as “acceptable” have often been challenged or found to be based on contradicting evidence. How best then to widen the net of social responsibility for innovative food design?

Based on their ongoing need to ensure profitability in a fiercely competitive market, whole sectors of the food industry understandably incite and encourage individuals and retail or institutional food purveyors (e.g., hotels and restaurants, schools, hospitals) to choose certain higher-profit margin foods over others, in spite of their doubtful nutritional value, at times

contributing to overall unhealthy lifestyles (e.g., overly high fat, sugar, or salt contents, vestigial traces of growth hormone).

Consumers find themselves making food decisions based on emotional aspects rather than rational ones, such as the actual nutritional value or safety of given products. While it is difficult to curb misleading information in the mass media, it is possible to counter them through public awareness campaigns about healthier and safer behaviors (Glanz et al. 1998). As to the media proper, outside the realm of direct advertising, they influence individuals and institutional customers in their relationship to food. It has been reported that television advertisements directly affect children’s eating habits and their food consumption (Arnas 2006). Prior research indicates that the media play a critical role in transmitting information to the public about the most pressing public health problems and framing attributions about who in society is responsible for solving these problems. For instance, it has been shown that the media served an important agenda-setting role in educating the public about the presence of trans fat in the US diet and describing the health risks these foods pose (Jarlenski and Barry 2013).

With a growing desire on the part of various societal actors and stakeholders to ensure better-informed decisions concerning the actual value of food products on offer, they will seek to take on more weight in the decisional matrix of what society perceives and allows as acceptably safe and nutritious food innovation. To keep in step with this evolution and better spread the burden of responsible technological innovation in the food industry, and thus increase predictability of innovation acceptance, food corporations will gradually move toward Value Sensitive Design implementation so as to ensure greater harmony between their mission statement and societal values, in the end better ensuring their long-term survival, which can come to be threatened by short-term profit orientation combined with post hoc strategies to convince various stakeholders of the innocuity of their innovative food designs.

In brief, to help innovation succeed, it is important to ensure an increasingly responsible process of innovation in which stakeholders are

collectively accountable to other stakeholders within a process fully embedded in the societal value matrix, including a focus on the health and safety of anything that ends up on the dinner table, and Value Sensitive Design is a means to actually operationalize social values within an ethical design process.

Innovation and Risk in the Food Sector

Food sector innovation is both product innovation *and* process innovation. The trend toward increasing vertical integration of food production, from seed development, farm crop production, food processing, and distribution, continues to evolve. This trend coexists with the concentration of development and production by an ever smaller number of corporate parties, partly due to the increasing scientific complexity of food product development and the associated need to quickly achieve economies of scale (Hellstrom 2003). With increasing advancements in technoscientific capability and market organization, the food sector may generate risks that could be difficult to assess or predict. The risks to society from food production arise along an increasingly science- and technology-dependent value chain but also with corporate practices that resort to emerging technologies with indeterminate health impacts. In such a context, the food sector is facing a number of difficult scientific, technological, socio-sanitary, environmental, and economic challenges. If the latter are not responsibly addressed, they may have systemic repercussions and harm societies' ability to provide healthy and nutritious food for their citizens. The transformations in market structures, modes of production, and distribution are often presented as increasing the rationality of food sector innovation. However, it is not yet clear what type of impact technoscientific capabilities, such as the genetic modification of crops and livestock, may have on individuals' health or on the environment. Popular understanding of these capabilities is often partial or biased. Despite the uncertainty of benefits and risks of these technoscientific advances, concentration in the market does not

favor options such as organic or integrated farming systems, but rather promotes riskier technologies in order to remain competitive. Even if institutional customers' and consumers' expectations about food safety have generally increased, the additional costs linked to improved health and safety often constitute barriers to healthier food. Overall, the incentives to promote an eco-healthy food sector are weak.

Risk management becomes increasingly difficult when the desire to innovate outstrips the ability to assess and absorb the risks (Smith 1992). Due to the coevolution of technological innovation and risk in the food sector, many new risks seem inevitable and impossible to predict. Some authors even consider that the interpenetration of complex technologies and daily life makes risk a greater part of reality (Beck et al. 1994; Lash 1994). If this is the case, should it be recommended to go beyond traditional risk assessments founded on observationally grounded science and include broader approaches, taking into account public involvement (through awareness, negotiation, facilitation, regulation, and monitoring), Value Sensitive Design, in brief, the infrastructures through which the agro-food innovations pervade socioeconomic life? While a precautionary approach has been proposed, such an approach does not seem viable because it would generate restrictions on food sector innovation (Hellstrom 2003). A systemic approach, namely, one that can better assess the unanticipated consequences of existing or new technologies, seems to be more appropriate for reducing technological risks while promoting responsible innovation. Such an approach could take into account the chain of risk factors in conjunction with the cycle of innovation in a variety of areas. One thinks of, among others, the insufficient knowledge of key regulatory stakeholders, which can affect a system adversely, or the marginalization of specific groups with knowledge, interest, or indirect bearing on a system, or still minimal support for public officials or corporate managers who have the potential to enforce measures to better balance benefits against risks in the corporate pursuit of profit (McEntire 2001).

Value Sensitive Design in the Food Sector

In order to encourage responsible food sector innovation, a Value Sensitive Design approach goes beyond profitability (and the relevant efficiency and usability requirements) to take into account the wider socioeconomic context, i.e., the consequences and risks as well as viewpoints about how science is related to technology and society, making it somewhat easier to anticipate some of the consequences of innovation (Korthals 2011). It becomes a proactive form of responsible innovation where peripheral experts, industry representatives, and lay publics are called in to help shed light on the consequences of new proposed technologies, resolve problems of risk assessment and management practices, provide new cognitive frameworks for complexity reduction, and suggest new ways of managerially drawing the boundaries of emerging technological systems (Funtowicz and Ravetz 1993; Hellstrom 2003). However, such an approach calls for a high level of mutual trust and sustainability. It is known that personal choice is pivotal in moving society toward a more sustainable food future, and it could be argued that sustainable food producers are looking to give consumers opportunities to make a positive impact. However, producers and consumers are often unable to connect because of the lack of reach or consideration or exposure for various initiatives.

Just as converging technologies bring forth synergistic innovations which can be highly unexpected and sometimes risky, so could this convergence inspire the very design process from the outset. This willingness to imagine the food sector as a “convergence of technologies,” crossing traditional boundaries between fields or disciplines, is vital to the success of the food sector. “Converging Technologies” is a label used to point at synergies between originally separate fields leading to revolutionary innovations and thereby new impacts (Houdy et al. 2011). In the food sector, the convergence of high-tech disciplines makes it increasingly difficult for specialists in one field to assess the work of others also involved in the process. Multiple ethical and social issues arise

that need attention and the traditional way of addressing these issues is becoming problematic as the roles and stakes change due to the developments instigated by technological advances. For instance, it has been suggested that instead of conducting an ethical evaluation after a genetically modified food has been marketed, it could be incorporated into the design phase. In this way, researchers and producers can recognize their responsibility to address the ethical issues involved in food sector innovation (Timmermans et al. 2011). Value Sensitive Design does justice to this shift of responsibility in addressing ethical issues at an earlier stage in the life cycle of innovative food developments. It supports design processes that take into account rapid technological development, on the one hand, with uncertainty and urgent ethical concerns, on the other.

Value Sensitive Design starts from the premise that technological applications are value laden in the sense that they have a morally relevant impact on individuals and society (Van den Hoven and Weckert 2008). Acting in accordance with moral values such as freedom, trust, or fairness is facilitated or constrained by technology (Timmermans et al. 2011). Where other design frameworks focus on functional requirements such as usability, efficiency, or speed, Value Sensitive Design primarily and specifically focuses on values and requirements of moral import. For instance, by including the moral values of trust and fairness and implementing them into the design, first, ethical issues can be addressed in the design phase and, second, relationships between the producers and the organizations promoting a sustainable food sector can be enhanced and lead to a much greater awareness of, and access to, food choices for people and communities as a whole. By working together, a more trustworthy relationship is achieved and a wider network of support established toward the goal of a responsible innovation in the food sector.

Among other principles, Value Sensitive Design calls for inclusiveness of and openness to all stakeholders and accountability of researchers and other promoters, due to the social, environmental, and human health impacts that their work may have on present and future generations

(Houdy et al. 2011; Timmermans et al. 2011). Stakeholders' involvement is a key feature of Value Sensitive Design. At present, the traditional actors involved in the food sector are not able to assess and control the technological artifacts. The burden of responsibility shifts to technological specialists involved in design and implementation. Value Sensitive Design offers a methodological stance that can help to bridge the gap between responsibility and design in the food sector. It is an operationalization of social values within the design process. This methodological stance, not bound by specific applications or issues, provides a general approach to deal with human values in innovative design processes. For instance, in the conceptual investigation stage, one inquires about how the technology could both benefit and negatively impact stakeholders, whether the latter interact directly with a technology or are peripherally connected to the technology. By connecting the values discerned to specific stakeholders, a more specific picture is drawn of the impact of any given innovation.

Social Responsibility in the Food Sector

The food sector relies on the creation and maintenance of consumer trust. Growing consumer awareness is demanding greater transparency and accountability from the food industry, and corporations must demonstrate their willingness to be held accountable for the quality and long-term safety of their products. To keep up with these demands, corporations have engaged with research organizations in new ways of innovation or have deliberately integrated social, environmental, and health concerns in their business operations. A number of studies have argued that such strategic management – through the use of social, environmental, or sustainability drivers – can be a route to responsible innovation, to create new products, services, processes, and new marketplaces (Little 2006; Mahlouji and Anaraki 2009). Other studies have reported that companies that do not take into account the increasing importance of social responsibility may not survive, in much the same way as those who fail to innovate

(MacGregor et al. 2007). However, other commentators consider that some aspects of socially responsible innovation could be incompatible with certain types of innovation. For example, Midttun (2006) argued that in the case of disruptive innovation – innovations that improve a product or service in ways that the market does not expect, typically first by designing for a different set of consumers in the new market and later by lowering prices in the existing market (Christensen and Rayner 2013) – firms have to change rapidly and as a result, they may disappear in a competitive market. In such circumstances, it might be difficult to combine competitiveness and responsibility objectives. Disruptive innovations often rely on new techniques or technologies, for which scientific knowledge is still limited and for which all consequences cannot always be foreseen. For instance, the impact of certain food innovations, which are now used in many consumption products, is still uncertain, and the consequences on health and environment are not precisely known. Responsibility, through the ability to understand and anticipate the consequences of actions, is a major criterion which should be integrated in innovation models, and especially in disruptive models, where anticipating consequences is a major challenge and where the integrity of individuals is at stake (Pavie and Egal 2010).

Most of the time though, it has been shown that the ripple effects of engaging in responsible innovation are unlimited and the benefits multiple, and not only for corporations (Business for Social Responsibility 2010). In fact, the strong demand from the market for quicker product or service development can threaten responsibility in the medium or long run (Pavie and Egal 2010). The more rapidly decisions are made, the more responsibility is needed to balance the risks. Therefore, corporations being aware of market pressure and time constraints, responsibility should remain a strong concern in the innovation process. Moreover, it strengthens accountability, helps improve quality of life, increases opportunities, empowers people, and is an investment in communities. While the concept of social responsibility is often associated with business practices, meaning

that companies should contribute to the welfare of society and not be solely concerned with making a profit, it is the people who run businesses. Therefore, responsibility begins with the people. And in regard to food, since food is fundamental to human life and a vehicle for improving health and welfare, everybody – as stated by the American Dietetic Association – needs to be responsible (Rodriguez 2010), whether they work in production, processing, preserving, or presenting food products. According to another organization, Business for Social Responsibility, since the production, distribution, and sale of food and beverage products affect global sustainability issues, ranging from access to water and workers' rights to hunger, poverty, health, and wellness, companies need to understand these impacts in order to devise effective strategies to promote sustainable farm-to-fork food chains and to meet the demands of customers, investors, NGOs, and government regulators (Business for Social Responsibility 2010).

Summary

There is no clear agreement on how to regulate the application of new technologies in the food sector. The risk assessment and management of these technologies have to take into account a complex array of human needs, economic interests, technoscientific uncertainties, and political responsibilities. One of the key considerations will be how far regulatory authorities are willing to compromise between competing stakeholder interests (Hellstrom 2003). The positions of all the actors involved, from the farmer to the consumer, need to be analyzed, in connection with the scientific and ethical implications of the new technologies, so as to identify how to encourage responsible innovation, despite the uncertainties. The diffusion of a new technology is not only a matter of technical progress but also of public approval and policy. As other authors have pointed out, because of their systemic intersection between technology, society, and market, food sector policies will have to reflect safety goals, state technological limits, and requirements as

well as outline ethical issues (Foray et al. 2012; Hellstrom 2003).

Value Sensitive Design widens the sphere of responsibility within any innovative process, better integrating the unforeseeable impacts of emerging technologies into the social fabric from the outset, anchoring the process to the contextual set of values of the society within which the innovation may spread.

[Food columnists](#); [Food journalist](#); [Food writer](#); [Restaurant critic](#)

Introduction

The most famous of the American restaurant reviewers are those who work at the *New York Times*. The national newspaper has largely set the standard for restaurant reviewing and food criticism. One of the most well-known critics is Craig Claiborne who became the food editor of the *Times* in 1957 and began using the star reviewing system (Claiborne 1982). On May 24, 1963, Claiborne first used a three-star scale. He added a fourth star a year later without explanation. The use of stars in a restaurant review was copied by newspapers across the country and is commonly used today (McNamee 2013). Some culinary historians have regarded the role of restaurant reviewer to be similar to theater or book reviewers at newspapers (Davis 2009). Journalism historians consider food critics to be part of the women's pages of newspapers until the mid-1970s (Voss and Speere 2013, pp. 41–50).

There is no specific training for a professional restaurant or food critic. The *Village Voice's* restaurant critic Robert Sietsema said that that being a journalist was the best preparation for the role. He said: "We're reporters who happen to write about food." *Washington Post* restaurant reviewer Tom Sietsema said he received his training from his predecessor food editor Phyllis Richman. He said: "I learned what a good story was. I got to test the bulk of the recipes for the paper. I was making no money but I was eating very well" (Raskin 2012). Richman also said that journalism ethics were central to her approach to criticism: "I hardly ever use the first person in my reviews. Perhaps it's out of

some traditional journalistic priggishness on my part. But I think it's appropriate that there be a distance and a sense of objectivity in that distance" (Dornenburg and Page 1998, p. 165).

Growth of Restaurants

By the 1800s, various incarnations of Delmonico's were established in New York City; some consider it America's first great restaurant. Antoine's opened in New Orleans in 1840, which was a move away from New York having all of the premier restaurants. The Michelin Guide to restaurants began using a star-rating system in 1926. Prohibition which forbids the consumption of alcohol hurt restaurants and led more people to eat at private clubs. Another significant moment in restaurant history occurred when Henri Soule's Le Pavillon opened in New York City in 1941. According to the *New York Times* food editor Jane Nickerson, there were more than 21,000 restaurants in her city by 1949. She wrote: "They serve to the city's residents and guest foods in so many languages as to rob the city of any one set of distinctive dishes." She went on mention Polish, French, Italian, Chinese, and German restaurants (Tracy 1952, p. 143).

The growth of fast-food and chain restaurants occurred in the 1950s and the 1960s. Typically, these eateries are not reviewed as the business model is for food to taste the same at each franchise. A few chain restaurants have been reviewed. The *Grand Fork Herald* reporter Marilyn Hagerty's March 7, 2012, review of the new Olive Garden in town turned into national news. Soon after it was posted online, the review had gone viral – picked up by Gawker and mentioned on numerous blogs (Hagerty 2012). Before long, there had been more than a million page views of the article, and the reviewer ended up as a judge on the television show *Top Chef*.

Food Reviewing History

Likely the first American restaurant reviewer was Duncan Hines – in the years before, he went on to

help found the cake mix company that bears his name. A traveling salesman, Hines would take notes about the places where he dined and what he ate while on the road. In 1935, he and his wife first included short reviews of diners and other eateries on the back of their Christmas card. The following year, he published his reviews in the booklet "Adventures in Good Eating" which went on to be published in 46 editions. The reviews were brief and largely focused on the menu. For example, in 1939, he wrote about Colonel Sanders' Café in Corbin, Kentucky. (This was before Sanders began his Kentucky Fried Chicken franchises.) Hines noted that it was a good place to eat "sizzling steaks, fried chicken, country hams and hot biscuits, 60 cents to \$1." Later, he collected recipes from the places where he dined that led to a three-times-a-week syndicated newspaper column "Adventures in Good Eating at Home" (Reynolds 2012).

For decades, most restaurant reviewing was about local eateries and restaurant criticism ran in the women's pages of newspapers. In later years, there would be stand-alone food sections. One of the most well-known food journalists in the 1940s through the 1960s was Clementine Paddleford who reviewed restaurants and wrote about food for the *New York Herald Tribune* (Alexander and Harris 2008). Often in her own plane, she flew to different cities to write about home cooks and what was served in restaurants. While in Milwaukee, for example, she wrote about the city's famed Mader's restaurant which had been serving German food since 1903. She described the history of the restaurant and included recipes for Sauerbraten, potato dumplings, and cheese torte (1960, pp. 346–347). In a 1964 column, she wrote that she had visited 36 countries searching for the best restaurants but found that the top eateries were in Manhattan. She explained: "The exploring gourmet can eat here in lavish elegance or in quiet simplicity" (Paddleford 1964, p. 148). The newspaper food section normalized the otherwise exotic dishes, the growth of restaurants, and the increasing trend of eating out. The dishes were unique to the demographics of those who lived in the readership area versus national food-related magazines.

In 1964, the *New York Herald Tribune* published a collection of columns from its top writers including Paddleford who noted that “restaurants are my beat.” Of the 18,000 eateries in the city, she detailed her 100 favorites. Rather than being negative about a restaurant’s failings, she focused on what was best. In the French category, she recommended Café Argenteuil. She wrote: “My favorite appetizer there is Baked Clams done garlic and herbs, with a dash of lemon and Pernod.” She wrote that at Le Veau d’Or, 90% of the customers spoke French. She gave three stars to Italian Pavilion. Of Michael’s Pub, she wrote: “When a pub becomes famous in New York City you can bet your buttons it’s quite a place.” Rather than being anonymous, she went into the kitchen to speak with the chef. At Karachi Restaurant, she described the chef bending over his curry pots (1964, pp. 147–148).

Jane Nickerson was the first person to review restaurants for the *New York Times*; she was the food editor from 1942 to 1957. The pre-Claiborne food section had been thought of as being largely fluff. Then in a journalism industry publication, former *New York Times* food journalist Molly O’Neill credited Nickerson with being one of the first food journalists to apply ethics and news values to her craft. According to O’Neill, news was central to the story lines in the vast majority of the *Times*’ food stories during Nickerson’s tenure. During one period early in the 1950s, 646 out of 675 food stories possessed a news hook, as catalogued in the *New York Times* index, and the percentage remained the same throughout the 1950s (2003, pp. 38–45).

When Nickerson reviewed restaurants, her dinner partners often included popular chef and cookbook author James Beard and longtime Associated Press food editor Cecily Brownstone. At that point in the 1940s, the reviewers ate for free at the restaurant and the focus was on the best dishes rather than a focus on the negative elements. It was a practice that changed after the Charles Van Doren television scandal in the late 1950s – made famous by the 1994 movie “Quiz Show.” He confessed to cheating on the popular quiz program *Twenty-One* in front of the Congress. In the aftermath, many media outlets,

including the *New York Times* and the Associated Press, strengthened their ethics policies. In part, this meant that critics could no longer accept free meals at restaurants as it was perceived as potentially slanting the review.

Restaurant Reviewing Culture

American restaurant reviewing has long been based on the critic maintaining a high level of anonymity. Like the reviewers of the future, Hines said that he tried not to be recognized so that he did not get preferential treatment. For example, he used a photo that was two decades old on his book jacket. He did, however, ask to see the kitchen after his meal. He wrote: “Food is a matter of taste. Good food is fresh, carefully prepared under sanitary conditions” (1955, p. 30). Staying anonymous is a key to ethical reviewing for most critics. The goal is to experience the restaurant the way an average customer would experience it. To demonstrate how different a dining experience can be when a critic is known, consider *New York Times* critic Ruth Reichl who had two different experiences when she ate in disguise and later as herself; she wrote about both meals and how critics tend to get better treatment than an average diner.

Some of the restaurant critics wore disguises while dining. Mimi Sheraton who followed in the footsteps of Claiborne at the *New York Times* wrote that she worked hard to preserve her anonymity for as long as possible. She turned down all invitations to restaurant-related events, wore a wide-brimmed hat for press photos, and never appeared on television without a disguise. Reichl not only ate in disguise, she created different characters, which she outlined in her 2005 memoir, *Garlic and Sapphires* (Reichl 2005). The concept of using disguises may be a gendered one. *New York Times* restaurant reviewer Pete Wells wrote that he does not wear a disguise as the hair pieces for men tend to be of poor quality and would draw attention to the person wearing it. He wrote in 2012: “Anybody can spot those from across the street. The whole point of a disguise is to make you inconspicuous” (Wells 2012).

Richman was able to dine anonymously for the first 5 years she reviewed restaurants in Washington, D.C. She said her gender helped her: "There were hardly any women reviewing restaurants in the 1970s, and restaurants did not recognize women." After the *Washingtonian* Magazine ran her photo, she was recognized more often. She said that she did not think it impacted the meal, other than portions being larger and with more garnish. Quality appeared to remain the same. She said: "It just astonishes me how much obviously bad food I get when I am recognized in restaurants" (Dornenburg and Page 1998, p. 44).

It is common for restaurants in America to keep a photo of the area newspaper critic in the kitchen in the hopes of spotting him or her. The need for anonymity is an American concept. French critics call ahead to let a restaurant know he or she is coming. In Britain, the photo of the restaurant critics runs next to their columns. The point is to impress the critic with the chef's best performance (Parsons 2010).

The American restaurant reviewers typically make reservations under false names and use various phone numbers. They paid using cash or credit cards in other names. The reviewer typically brings guests so that several dishes can be sampled at the same meal. According to current *Los Angeles Times* food editor Russ Parson: "This ensures that a restaurant has minimum warning that a critic is coming, on the theory that there is little that can be done once he or she is in the door. There is no way for a chef to dream up some super-elaborate dish or acquire higher-quality ingredients at the last minute" (2010). On the other hand, at the *New York Times*, Sheraton was asked what a chef could do on short notice to improve a meal when a reviewer is spotted. Her answer was: "Just about everything" (2004, p. 104).

The internet has begun to chip away at the ability for a reviewer to remain unknown. In December 2010, the *Los Angeles Times* published an article in its food section about the public outing of its food critic. One of the owners of the new Beverly Hills restaurant Red Medicine created a firestorm by confronting *Times* restaurant critic S. Irene Virbila while she was waiting for a

table. Her photograph was taken and her party was kicked out of the restaurant. The photograph was then posted on the Internet. A newspaper article about the evening noted: "By the next morning, more than 15 years of working to remain anonymous were ruined" (Reynolds and Lynch 2010).

To be ethical and fair, most critics follow the recommendation that the restaurant be visited three to five times before a review is written. Claiborne initially dined at a restaurant twice before reviewing it. He later added a third visit. Some newspapers will wait a certain amount of time after a restaurant opens before they review it. At the *Los Angeles Times*, the policy is to wait a 3-month grace period "to get the kinks worked out before reviewing" (Parsons 2010). Other critics feel that if restaurant is open and charging full price for meals, it is fair to be reviewed immediately (Rousseau 2012).

The Association of Food Journalists includes ethical guidelines for restaurant reviewers on its website. The organization recommends: "Reviews should be conducted anonymously whenever possible. Critics should experience the restaurant just as ordinary patrons do." The organization also addressed ethical concerns about new restaurants: "To be fair to new restaurants, reviewers should wait at least 1 month after the restaurant starts serving before visiting. These few weeks give the fledgling enterprise some time to get organized."

Small-Market Restaurant Critics

While New York, Los Angeles, and New Orleans tend to dominate restaurant reviewing, most metropolitan newspapers employ their own restaurant critics. For example, Ruth Gray was the food editor and restaurant critic for the *St. Petersburg Times* in the 1970s (Gray 1975). She got into food writing after earning a degree in home economics from Kansas State University. She regularly reviewed restaurants in her "The Realm of Dining Out" and her "A la Carte" columns. She wore hats and scarves and ducked inside the ladies room to take notes and stay inconspicuous. When one server called her by name and said the meal was

on the house, she did not write the review. It was a busy beat. For example, between September 1974 and January 1977, she reviewed 118 local restaurants. She would take her husband and two to four friends to eat at the restaurant. She rated the restaurants based on quality of food, atmosphere, service, and price. Only four restaurants earned excellent in all areas that were evaluated (Witwer 1977).

One particular review led to a pile of letters in response, so many that an ombudsman editor's column was devoted to the review and response. Gray's review had begun with an account of what she believed to be rude treatment by the staff. Gray and her husband arrived on a rainy evening and by the time they entered the restaurant, their clothes were soaked. Gray had removed her wet coat and was treated rudely by the hostess. In Gray's review, she wrote that the embarrassment and indifference had impacted her meal. Readers wrote in to support the restaurant, arguing that the restaurant needed to have standards if it was to uphold its elegant reputation. Gray didn't back down from her assessment. "My assignment is to give a truthful account of my dining experience," Gray responded in an editor's column (Goldman 1978). Reviews that included treatment by a restaurant's staff, in addition to the food served, is typical protocol in the industry.

One of the best-known modern newspaper restaurant critics was Elaine Tait of the *Philadelphia Inquirer* who wrote restaurant reviews for 35 years. Upon retirement, said of the job: "I didn't realize how exhausting and invasive it was until I was out of it." She has a wheat allergy which prevented her from eating too much pasta or cake while reviewing. She recalled that "You have to have a full battery of people to go out with you, and it has to be a convenient location and time for them. People tend to get very blasé about it after a few times" (Ludwig 2011).

Food Magazines

Food magazines have been common for decades and often featured food criticism. *Gourmet* was introduced in 1941. While World War II was looming, the magazine focused on luxury rather

than the everyday work of home cooks. Its tagline was: "The magazine of good living." It was largely based on a male audience. As culinary historian Laura Shapiro wrote: "Haute Cuisine was strictly a male preserve in France, and America inherited the prejudice" (2004). Publisher Conde Nast closed the publication in 2009 after an almost 70-year tenure. The magazine *Food & Wine* was started in 1978 as a more down-to-earth alternative to *Gourmet*. Initially, it was called the *International Review of Food & Wine* which had a prototype published in *Playboy*. The magazine continues today, as does *Bon Appetit* which began in 1956.

A significant difference between the newspaper and magazine was the business models and ethical guidelines. At newspapers, there is a distinct separation between the editorial department which produced the food section and the advertising side of the publication. Advertisers cannot dictate what reporters write about, how something is written, or where an advertisement will appear in a publication. There is a looser relationship at magazines. Advertisers can dictate where their ad appears and what kind of stories it is advertising near in the publication. Further, newspaper journalists are more fact based than their magazine counterparts who may take a more creative approach. Reichl wrote that she learn that when she went from writing for a magazine where she could invent dinner partners to writing for newspapers where she needed to take a different approach (2012, p. 32).

Democracy of Restaurant Reviewing

A new democracy for food and restaurant reviewing was on its way even before the internet. In 1979, Tim and Nina Zagat started distributing their restaurant reviews based on a poll of customers. Rather than the experts from newspapers or magazines, regular consumers judged the eateries based on food, decor, service, cleanliness, and cost. A 30-point scale was used to evaluate the restaurant. Initially they self-published the Zagat Guide and distributed it through individual bookstores. By the 1980s, they were publishing

commercially and caught the New York restaurant community's attention. They sold 75,000 copies per month in 1986. They went on to survey restaurants across the country. In 2011, the company was acquired by Google and reviews are integrated into Google Maps and Google+.

Today, reviewers can check in on social media sites like Yelp, Foodspotting, or Foursquare and describe their meals and service experiences. Research has found that about 45% of consumers have already decided where to eat with the help of an online dining guide (Pan 2012). Online reviews are significant in deciding what's for dinner – 57% of patrons rely on them. This does not mean that the system is democratic. There are numerous public relations firms that offer services to eliminate or bury negative reviews and to increase positive reviews. Signe Rousseau examined the interaction between food and individual reviewers in her 2012 book, *Food and Social Media*. She wrote: “The main narrative around social media and food criticism concerns the fact that, as the saying now goes, everyone is – or at least can be – a critic.” The legal and ethical implications of this new model are still being debated.

Summary

Restaurant reviewing or food criticism is a written critical analysis of culinary dishes or eateries. Both terms are used to describe a critical, evaluative opinion that often involves some kind of rating system. Women's magazines and the food coverage within have been studied to some extent, but the same generalizations drawn from those works cannot necessarily be applied to newspaper food sections. The two media forms usually operated quite differently in its separation of the editorial and advertising relationship. Further, a newspaper has a local readership unlike a national magazine.

Introduction

Restaurant workers include a diverse group of occupations and jobs that contribute to the operations of a restaurant. While tasks and occupational demands vary according to each specific position, there are issues that are shared among all workers. These issues include low pay, long hours, occupational and safety hazards, recognition for their services, and representation in the wider workforce.

Background

Restaurant workers are classified as individuals who work within the wider leisure and hospitality industry at the site of a restaurant. What constitutes a restaurant is open to interpretation. Broadly speaking, a restaurant is an eating place where meals are served to customers. Depending on the interpretation, there have been different dates named as the establishment of the first restaurants.

However, the founding of what many consider to be the modern ideal of a restaurant is dated to eighteenth-century France. The term restaurant evolved from a dish. In eighteenth-century France, a restaurant was a quasi-medical bouillon, a type of restorative broth. Restaurateurs' rooms were opened, specializing in the preparation of these broths (Spang 2000). They also provided other fare and became popular in post-revolutionary France. What distinguished these eating houses from that prior is that modern restaurants were places to be seen as much as they were places to dine. Moreover, they were located in urban centers and became part of the social landscape.

The first restaurants in America originated in the late eighteenth century. These were originally modeled on those developed in France. They were found in the cities of Boston and Philadelphia and later spread to other metropolitan centers.

These early dining spaces in France laid out the signature elements of modern restaurants. Restaurant cultures thrive in urban centers, although they can also be found in smaller towns and villages. They provide a selection of prepared food for clientele and are social spaces as much as they are commensal spaces. Today, the restaurant can even be considered part of the entertainment industry as it is heavily involved in the selling of desires and moods alongside the selling of its food.

Contemporary restaurants have evolved from their eighteenth-century origins. Today in the United States, restaurants are part of what the Bureau of Labor Statistics calls food services and drinking places. The range of modern restaurants includes full-service restaurants as well as limited-service eating places; cafeterias, grill

buffets, and buffets; snack and nonalcoholic beverage bars; special food services; and drinking places serving alcoholic beverages. Although fast-food restaurants and fine dining restaurants serve dramatically different clientele at different price points, many of the occupational issues, hazards, and ethical quandaries exist across different dining venues.

Restaurants have a significant financial impact on local and national economies. In the United States, it is the largest private sector employer. Across the country there are 980,000 locations of restaurants with 13.1 million employees. The industry is predicted to bring in \$660 billion dollars of sales in 2013. Restaurants are a popular form of small business as they have low start-up costs and relatively few institutional barriers to entry (Fine 1996). In the United States, 93% of restaurants employ less than 50 individuals.

Depending on the needs and size of establishment, the types of restaurant workers employed will vary. They can include bartenders, chefs and head cooks, station cooks, food and beverage servers, food preparation workers, and waiters and waitresses. Overall, these jobs require little entry-level education. In the United States, the only notable difference is that the entry-level education required for a chef or head cook was nominally higher, at the level of a high school diploma or equivalent. Most require less than the equivalent to a US high school diploma. Pay for these occupations are also largely low, with median pay at approximately \$20,000 US dollars as of 2010. In 2010 median pay for a bartender was \$18,680; a waiter or waitress earned around \$18,330. For a cook that figure would rise to \$20,260. Among restaurant workers, chefs and head cooks earn the most with median pay around \$40,630. Overall restaurant jobs represent 7 of the 11 lowest-paying occupations in the United States.

Barriers to Entry

There are few barriers to entry to restaurant occupations. As a result, the restaurant industry has a diverse workforce, employing significant numbers of women; immigrants, including

undocumented immigrants; and ethnic minorities. In the case of new immigrants and undocumented immigrants or groups like the physically challenged or mentally handicapped, restaurants become one of the few places for employment (Fine 1996).

It is also a widely accessible form of employment. Roughly one-third of Americans gained their first work experience in a restaurant and half of all adults have worked in the restaurant industry at some point in their lives. In particular fast-food restaurants and chain restaurants employ large numbers of new jobseekers because they do not require previous relevant work experience. Because of the accessibility of restaurant work, there is a common misconception that restaurant workers are young people earning extra spending money or saving for higher education (Jayaraman 2013). In actuality workers represent a diverse range of ages and skillsets, and many remain in the industry for decades.

While there are educational institutions that provide training in some of the restaurant trades, such as culinary schools, bartending academies, and wines certification programs, they are not necessary for this industry. Among cooks and chefs, some receive training through formal and informal apprenticeships. This remains a strong tradition in Europe where cooks would be educated on the job, although this practice is less common in other parts of the world. Even in today's culinary industry, this tradition continues to persist. Short-term informal, often unpaid, work experience called a stage may be taken to expose one to different culinary ideas or to network and develop contacts. It has been argued that having a formal education is useful for promotion, particular among cooks seeking future administrative or managerial positions.

While restaurant work has become a trendy occupation among the middle and upper middle classes in the United States (Zukin 1995), workers in this industry still come primarily from lesser socioeconomic and underrepresented backgrounds (Fine 1996). Women represent approximately two-thirds of workers in tipped occupations in 2011 in the United States. Women of color, notably Black and Hispanic

women, are disproportionately represented among these numbers. Although the restaurant industry is one that has a diverse workforce, discrimination on the basis of race, gender, and other factors have created inequalities.

The Restaurants Opportunity Center has found that white applicants were nearly twice to receive job offers and earned nearly 12% more than workers of color. Male workers also earned nearly 22% more than female workers (2009). Notably in New York City, discriminatory hiring practices are often used to control the “symbolic economy” of the restaurant (Zukin 1995). High-end restaurants have a preference for hiring young people of European-American heritage with artistic backgrounds for front of house staff under the guise of enhancing the atmosphere of the dining room. Back of house positions are also plagued by inequalities. In the United States, only 19% of chefs are female. Male executive chefs earn \$18,000 more per year than their female counterparts. And while the restaurant industry in the United States may employ workers from a range of ethnic backgrounds, very few minorities are visible in positions of power or leadership. Few attain the position of head chef outside of ethnic restaurants.

Categories of Restaurant Workers

Restaurant workers are generally divided into three categories: front of house or those whose duties fall primarily within the dining room; back of house staff or those who work in the food preparation and kitchen areas; and management, a category which includes the owners of the establishment. While all types of restaurant workers are involved in the everyday production of food and service to customers, their occupational identities and occupational challenges differ based on their roles in the environment.

Within restaurant operations, their tasks, occupational identity, and responsibilities are designated according to whether they are front of house or back of house workers. Those working in front of house positions deal primarily with customer service, although they also liaise with

management and food preparation staff. Those employed in back of house positions are primarily responsible for food preparation and production, although they will collaborate with management or front of house staff in matters of food and beverage pairings, service efficiency, and other issues that concern restaurant operations as a whole.

Restaurants employ systems of hierarchies to distinguish one restaurant worker from another. Many formal French kitchens are organized through a brigade system, a system of rankings based on military hierarchies invented by Auguste Escoffier in the nineteenth century. Kitchen workers were ranked according to task and status, with a chef serving as a top commander. Even in those kitchens that lack some of these formal distinctions, there is an element of distinction between different tasks and different responsibilities held among chefs. These hierarchies are significant because chefs are often publicly recognized for their labor, with some attaining celebrity status (Rousseau 2012). Meanwhile those who work in lesser ranks, such as dishwashers and pot washers, receive limited recognition for their work. Although these workers perform critical operational tasks, often serving as the “backbone” to operations, they are rendered largely invisible in the eyes of the public.

Servers, sometimes called waiters or waitresses, are another highly visible category of food worker. These front of house workers interact directly with restaurant clientele. Their tasks include serving food and beverages and some cleanup of the dining space. Their roles also include interactions with kitchen staff in the back of house: placing food and beverage orders, communicating customer requests, and some food preparation. While this group of workers is the most “public” because they deal directly with customers, they too are often rendered “invisible” because of their servile roles (Cobble 1992; Paules 1991).

Though excluded from the United States Bureau of Labor Statistics’ classifications, restaurant workers can also include managers, service directors, and other managerial or administrative staff. These individuals, however, are not counted

officially as restaurant workers in the US Bureau of Labor Statistics' classifications. Nor are they thought of to be on the front lines of restaurant work, through either the food preparation end or customer service. These individuals often earn more than their counterparts. Also excluded are those who provide extraneous services. They may be part of the restaurant atmosphere but are not counted as restaurant workers. These positions include the coat check attendant or parking valet. Also left out of this classification are sommeliers or wine stewards and sanitation and cleaning staff, which also are responsible for the upkeep and running of a restaurant.

Status and Professionalization of Restaurant Workers

Public perception of restaurant workers is mixed. Although in the United States and Western Europe there has been a growing awareness of food culture through the popularization of cooking shows, food magazines, and food blogs, this reflects the lifestyles of a very limited few in the restaurant industry. Sociologist Gary Allen Fine's study of restaurants in the Twin Cities area revealed conflicting viewpoints on the public perception of cooks. Fine's restaurant industry informants revealed that some cooks believe that the public does not respect them and that they would face difficulties transitioning to a professional job if they chose to leave the restaurant industry. Others feel that they are recognized as artists (Fine 1996). Cooks and kitchen workers report the emotional satisfaction as one of the positive elements of their work. There is high self-satisfaction and the public acknowledgement of their work, through restaurant reviews, write-ups, blog posts, and word-of-mouth comments. Restaurant work is also highly mobile and employment is relatively flexible, as culinary skills are portable.

Restaurant workers have been parodied in popular media. Many of these portrayals of restaurant workers have been negative. Strong stereotypes in service work exist, such as the trope of the rude or incompetent waiter (Bell and Valentine 1997).

Some restaurants have used it to their advantage as a marketing gimmick. Edsel Ford Fong, a waiter at the former Sam Wo Restaurant in San Francisco, was legendary for his brusque service and was nicknamed the world's rudest waiter. However, most of these stereotypes are used to suggest incompetency rather than an act performed by the worker.

Cooks and chefs, in particular, have seen their share of stereotypes. Sometimes these stereotypes are promoted and aggrandized as part of a glamorous, "rock 'n' roll" lifestyle. Celebrity chefs like American Anthony Bourdain and British Gordon Ramsay have played up these characterizations to the advantage, using it as a scripted form of personality for the media. However, these stereotypes reveal an underlying issue in the public image of cooks. They have been, throughout various historical periods, viewed as problematic or troublesome. To deal with the problematic character of cooks and restaurant workers, there have been attempts to reform the industry through the establishment of standards.

In the Western culinary world, the matter of "professionalization" has been a part of the discourse surrounding restaurant workers, particularly chefs, since the eighteenth century (Trubek 2000). The "professionalization" of cooks has resulted in the formation of chefs' associations and organizations, the establishment of cooking schools, and the adoption of industry standards that range from uniform to hygiene standards. Two of the most widely recognized symbols of a cook – a white chef's hat known as a toque and a white high-collared jacket – were adopted in the nineteenth century. Other elements of professionalization, such as the formation of a brigade system used in classical French kitchens, suggested a reporting hierarchy. It also helped generate status among different workers in a vocational kitchen setting. In other culinary contexts cooks were professionalized as part of political campaigns. In the former Soviet Union and in China, vocational cooking schools were established as a means to control and widely disseminate culinary knowledge. All of these discourses surrounding professionalism have impinged on the suggestion that cooks are morally deficient to some capacity

and needed to be vocationally reformed through the interventions of outside institutions.

Labor Conditions

Restaurant work is physically demanding. Issues of long hours, stress, pressure, poor working conditions are among the drawbacks of restaurant work. Working hours are long and workers can suffer from a range of occupational injuries. Kitchen workers are subject to burns, cuts, and other bodily injury incurred during the preparation of food.

Restaurant workers are often expected to work through injury, pain, and illness. Compounding the issue is that many restaurant workers are not given paid time off for illness or medical care, which is problematic in an industry where injury and illness rates are high. This has also caused debate about public health, as restaurant workers come in contact with customers and their food and can easily transmit illnesses. A Restaurant Opportunities Centers United study in 2010 found that 87.7% percent of restaurant workers in America surveyed were not given paid sick days. Nearly 90% did not have health insurance through their employer.

Cooks and kitchen workers are prone to injuries like carpal tunnel syndrome, tennis elbow, herniated discs, hip pain, and other conditions due to long hours and the repetitive nature of kitchen tasks. Many governments have legislation and bodies that govern workplace safety. In the United States, the Occupational Safety and Health Administration (OSHA) has standards to minimize workplace injury and a reporting mechanism to cite violators. While there are protective measures in place like rest breaks, nonslip shoes, or nonslip floor mats, restaurant work is still considered to be dangerous due to the physical demands and long hours required. Despite governmentally mandated safety measures, employers may violate the rules. The Restaurant Opportunities Centers United found that 38.1% of restaurant workers in America surveyed in 2010 were asked to perform tasks which put their own safety at risk.

Restaurant work is not only physically demanding, but it is also an emotionally

challenging job. Restaurant workers, especially front of house workers, are expected to “perform” and entertain restaurant patrons, providing a form of “emotional labor” alongside physical labor. Their job requires emotional management, from changing their surface emotional displays to controlling deep inner feelings to accommodate customer’ needs and to conform to management demands for hospitality. Servers, in particular, are often required to exhibit a high amount of emotional management. In countries where tipping is part of the social norm, emotional labor can directly impact income as customers often base gratuities on the level of emotional service received.

Unions and Professional Associations

There are organizations that recognize and represent restaurant workers. In various countries, restaurant workers can gain certifications as a mark of distinction or accomplishment. The French government awards a *Meilleur Ouvrier de France* (MOF) for accomplishment in specific trades. A food work is a category recognized, and cooking and running restaurants is a category for which one can achieve an award.

The American Culinary Federation provides certifications for cooks, chefs, and other culinary workers at different levels in the United States. This often is for those seeking advance certification leading to advancement and senior positions in a restaurant. Often these certifications can command higher salaries or serve as a recognizable accomplishment on a job application. But the drawbacks to obtaining these requirements include a minimum number of years of relevant work experience, letters of reference, application fees, testing fees, and fees to pay for tuition, travel, housing, and meal during the testing certification period that come out to estimated \$4,000–6,000, a sizeable cost in a what remains a low-wage industry.

Numerous other organizations exist representing the interests, including CulinaryCorps, the International Association of Culinary Professionals, the James Beard Foundation, the National Confectioners Association, the World Association of

Chefs Societies, Confrérie de la Chaîne des Rôtisseurs, and Les Dames d'Escoffier. Many of these associations cross professional lines, representing restaurant workers and other culinary professionals. Confrérie de la Chaîne des Rôtisseurs is a gastronomic society that boasts both industry members and those who are generally interested in promoting and developing the gastronomic arts. Many of these associations deal more with raising the public profile of cooks and restaurant workers and engage with the role of gastronomic development rather than addressing labor conditions.

Restaurant workers voice their labor and industry concerns primarily through unions. The Hotel Employees and Restaurant Employees Union (HERE) is an American labor union founded in 1891. It later joined with the Union of Needletrades, Industrial, and Textile Employees to form UNITE HERE in 2004. It represents major hospitality industry employers, including large casinos like Harrah's, Caesars Palace, Wynn Resorts, major hotel brands (Hilton, Hyatt, and Starwood), and Walt Disney World Resorts. Individual states and local districts have local chapters of UNITE HERE, such as the Culinary Workers Union located in Nevada with 60,000 members. Restaurant Opportunities Centers United is the largest worker center in the United States dedicated entirely to the concerns of restaurant workers. Around the world, there are also trade unions that represent hospitality workers and restaurant workers. For example, the Swedish Hotel and Restaurant Workers' Union has a membership of 61,000 members. While there are a number of labor organizations representing restaurant workers in the United States and globally, the majority of industry employees are not unionized and do not have collective and formal channels of addressing occupational concerns. Overall less than 1% of restaurant workers in America have no collective representation.

Fair Pay

Fair pay among restaurant workers is a source of contention. Workers are often expected to work

long hours. While many may only be paid for their legal working hours, which in the United States is an 8-h shift, restaurant workers are often expected to work longer than the legal time period with no overtime pay. Wages overall for the industry are low, as mentioned in a previous section. In America workers' wages have remained stagnant over the last 20 years, in part because the federal minimum wage for tipped workers remains \$2.13 an hour. Workers have been fighting to receive fair pay and the right to receive a "living wage."

A major controversy in the United States surrounds the matter of tipping. Servers and other front of house workers receive the majority of their pay through gratuities or tips. Many front of house restaurant workers are classified as tipped employees by the United States Department of Labor. Tipped employees are workers who customarily and regularly receive more than \$30 per month in tips. The Fair Labor Standards Act (FLSA) allows the employer to withhold a tip credit. In other countries, notably for some in Western Europe, servers are paid set hourly wages. Gratuity for service is often built-in to the bill or added as a standard service charge. Additional gratuity may be left at the whim of the customers, but it is not expected and the amounts are often small change. In some parts of the world, such as Japan, gratuity is not part of restaurant culture and may possibly cause offense. In Australia, tipping in certain establishments, such as a casino, can be constituted as a form of bribery.

In the United States, gratuity is not often built into dining costs and customers are expected to compensate front of house staff through the practice of tipping. This often amounts to 15–20% additional payment on top of the dining bill. Depending on the individual management policy, tips can be pooled among workers or distributed to individual servers. Tipping is meant to reward quality and efficient service; however, this practice creates much tension between restaurant workers. Kitchen staff normally do not receive any percentage of tips, even if they are pooled among workers. Pooling tips rewards higher amounts to servers and lesser

amounts to other front of house workers like bussers. Tensions between tipped and non-tipped workers can exist between restaurant workers. There can be resentment between these two groups, leading to conflict within the work environment. Many restaurants that participate in tipping do not require tipped workers to share their tips.

Legislation in the United States has regulated pay among workers who receive tips. The Fair Labor Standards Act (FLSA) requires a minimum wage of \$2.13 for tipped workers, compared to \$7.25 for nonexempt workers. Legally tips are considered the sole property of the tipped employee. However, restaurant workers have complained that the FLSA creates an unfair system, as employers can withhold tips. Furthermore, millions of workers have also experienced wage theft when they were not paid the wages and tips they were owed. Fair pay for restaurant workers has long been an issue of contention, which has affected restaurants at all socioeconomic levels.

Summary

In summation, this essay raises some of the issues currently faced by the diverse category of workers in the restaurant industry. While occupational demands vary across job segment in this industry, many of these problems are universal among all restaurant workers. Restaurant workers are receiving more attention for their efforts as issues of industry discrimination, labor conditions, fair pay, collective bargaining, and recognition of their labor are being addressed on a political and social level. Social media has raised attention to their plight, and unions and organizations continue to draw public attention to their causes. In the end, restaurant workers are a critical part of many economies while contributing strongly to the social landscape of a community.

Introduction

The *right to food* is a human right. It protects the right of all human beings to live in dignity, free from hunger, food insecurity, and malnutrition. The right to food is protected under international human rights and humanitarian law. The right to food has been defined as the right to have regular, permanent and unrestricted access, either directly or by means of financial purchases, to quantitatively and qualitatively adequate and sufficient food corresponding to the cultural traditions of the people to which the consumer belongs, and which ensures a physical and mental, individual and collective, fulfilling and dignified life free of fear (Ziegler 2008, 17).

With almost 870 million people chronically undernourished in 2010–2012, the number of hungry people in the world remains unacceptably high. The vast majority live in developing countries, where about 15% of the populations are estimated to be undernourished (FAO 2012). The right to food approach to food insecurity is based on the premise that tackling world hunger requires improving not the availability of food, but access to food for the vulnerable and deprived. Indeed, the lack of access to food is

almost never the result of a general scarcity of food. Instead, people are deprived of food because they have no opportunity to produce it, cannot earn a sufficient income to buy the food they need, or are unable to work at all (Künnemann and Ratjen 2004, 1). For this reason, the right to food approach calls for a specific focus on categories of people that are vulnerable or marginalized, such as the landless, the unemployed, the elderly, indigenous peoples, women, children, and people with disabilities.

Most accounts of the history of the right to food point to Franklin Delano Roosevelt's famous 1941 "Four Freedoms" speech as a starting point. The speech – which looked forward to a world founded upon four essential human freedoms (freedom of expression, freedom of worship, freedom from want, and freedom from fear) – is notorious because it set out the idea of civil and political rights and economic and social rights as part of an indivisible and global value system (Roosevelt 1941). The holistic notion of human rights was subsequently expressed in the Universal Declaration of Human Rights of 1948, which included the right to social security; to work; to rest and leisure; to an adequate standard of living, including food, clothing, housing, and medical care; and to education.

This entry presents internationally agreed definitions of the human right to adequate food, conceptual developments in the last decades, and an overview of the challenges facing the full realization of this fundamental human right globally.

Definitions of the Right to Food

The human right to food is recognized in Article 25, paragraph (1), of the Universal Declaration of Human Rights:

Everyone has the right to a standard of living adequate for the health and well-being of himself and of his family, including food, clothing, housing and medical care and necessary social services, and the right to security in the event of unemployment, sickness, disability, widowhood, old age or other lack of livelihood in circumstances beyond his control. (UN General Assembly 1948)

The right to food is also recognized in Article 11 of the International Covenant on Economic, Social and Cultural Rights (ICESCR), which came into force in 1976. The Food and Agriculture Organization (FAO) of the United Nations actively participated in the drafting of Article 11, and FAO's Director-General proposed the substance of what became paragraph 2 of that Article, which addresses the negative right to freedom from hunger. Article 11 reads:

1. The States Parties to the present Covenant recognize the right of everyone to an adequate standard of living for himself and his family, including adequate food, clothing and housing, and to the continuous improvement of living conditions. The States Parties will take appropriate steps to ensure the realization of this right, recognizing to this effect the essential importance of international co-operation based on free consent.
2. The States Parties to the present Covenant, recognizing the fundamental right of everyone to be free from hunger, shall take, individually and through international co-operation, the measures, including specific programs, which are needed:
 - (a) To improve methods of production, conservation and distribution of food by making full use of technical and scientific knowledge, by disseminating knowledge of the principles of nutrition and by developing or reforming agrarian systems in such a way as to achieve the most efficient development and utilization of natural resources;
 - (b) Taking into account the problems of both food-importing and food-exporting countries, to ensure an equitable distribution of world food supplies in relation to need" (UN General Assembly 1966).

In addition, the human right to adequate food is recognized in specific international instruments such as the Convention on the Rights of the Child (Art. 24(2)(c) and 27(3)), the Convention on the Elimination of All Forms of Discrimination against Women (Art. 12(2)), or the Convention on

the Rights of Persons with Disabilities (Art. 25(f) and 28(1)). The right to food is also recognized in regional instruments – such as the Additional Protocol to the American Convention on Human Rights in the Area of Economic, Social and Cultural Rights, known as the Protocol of San Salvador (1988); the African Charter on the Rights and Welfare of the Child (1990); and the Protocol to the African Charter on Human and Peoples' Rights on the Rights of Women in Africa (2003) – and in numerous national constitutions.

The right to food is to be distinguished from the concepts of "food security" and "food sovereignty." One of the most commonly used definitions of *food security* is that of FAO, which states that "Food security exists when all people, at all times, have physical and economic access to sufficient safe and nutritious food that meets their dietary needs and food preferences for an active and healthy life" (FAO 2008). Food security is the most widely used term in global debates about hunger and malnutrition; it is commonly used by UN agencies, development organizations, and governments across the globe. *Food sovereignty*, in turn, is a concept originally coined in 1996 by La Vía Campesina, a transnational social movement of peasant and indigenous organizations (Vía Campesina 1996). Food sovereignty calls for the rights of local communities and nations to decide their own food policies. A large number of actors, including governments, have integrated the food sovereignty concept into their terminology and have contributed to its further development. Today, the definition provided in the 2007 Declaration of Nyeleni is considered to be the most representative. Food sovereignty is defined as "the right of peoples to healthy and culturally appropriate food produced through ecologically sound and sustainable methods, and their right to define their own food and agriculture systems" (Nyeleni Food Sovereignty Forum 2007). Contrary to food security, food sovereignty is generally described as a rights-based concept, for it includes the right to food and the right to produce food, as well as a number of other associated rights (to land, resources, live in dignity, etc.) (Claeys 2012).

Normative Elaboration of the Right to Food

Following its international recognition, the right to food underwent a period of intense conceptual elaboration in the period ranging from the coming into force of the International Covenant on Economic, Social and Cultural Rights, in 1976, to the adoption by the FAO Council of “Voluntary Guidelines to Support the Progressive Realization of the Right to Adequate Food in the Context of National Food Security” in 2004.

A large number of such developments took place within the United Nations. In 1979, the UN Economic and Social Council (ECOSOC) began monitoring the right to food. In 1983, the UN Subcommission on the Promotion and Protection of Human Rights named Asbjørn Eide Special Rapporteur on the Right to Food. The same year, the ECOSOC commissioned a report on food as a human right, which began the process of adding clarifications and new implementing instruments. In 1985, the ECOSOC established the Committee on Economic, Social and Cultural Rights (CESCR) to receive country reports and monitor progress on implementing the International Covenant on Economic, Social and Cultural Rights (ICESCR). The Committee is composed of independent experts, serving in their personal capacity, elected by the states parties.

In the early 1980s, a number of committed civil society groups started working on specific economic, social, and cultural rights. In the NGO field, the foundation of FoodFirst Information and Action Network (FIAN) in 1982 was followed by the establishment of the Habitat International Coalition (HIC) in 1987, the Centre on Housing Rights and Evictions (COHRE) in 1992, and the Center for Economic and Social Rights (CESR) in 1993. FIAN International, which developed as an international network with its secretariat in Heidelberg, Germany, focused exclusively on the defense and promotion of the right to food. FIAN members substantively contributed to the conceptual debates on the right to food that took place at the UN and in academic circles. Yet, the organization rapidly developed its own interpretation of the right to food: from the

outset, FIAN insisted that the right to food be understood and implemented as the *right to feed oneself* (Künnemann 1984, 95). FIAN activists put a lot of emphasis on the situation of the rural poor (and small-scale farmers in particular) who constitute the bulk of the hungry and malnourished and on the importance of securing access to the means of producing food, such as land, water, and other natural resources.

In 1996, the World Food Summit convened in Rome reaffirmed “the right of everyone to have access to safe and nutritious food, consistent with the right to adequate food and the fundamental right of everyone to be free from hunger” (World Food Summit 1996). Responding to pressure from civil society organizations (CSOs), governments requested that the right to food be given a more concrete and operational content (World Food Summit 1996, objective 7.4). Two documents were released in the following years to provide a better understanding of the right to food: the General Comment No. 12 of the UN Committee on Economic, Social and Cultural Rights and the FAO Voluntary Guidelines to Support the Progressive Realization of the Right to Adequate Food in the Context of National Food Security.

General Comment No. 12 on the right to food was adopted in 1999 by the Committee on Economic, Social and Cultural Rights (CESCR). General comments aim to elucidate the Committee’s own understandings of the rights and obligations anchored in the Covenant (Riedel 2009, 143). General Comment No. 12 helped define the core content of the right to food and how states could implement the right to food domestically. The core content of the right to food is described by three A’s – *accessibility*, *availability*, and *adequacy*. While adequacy refers to the quality and nutritional and cultural value of food consumed, accessibility and availability address the means of acquiring food. *Accessibility* requires economic and physical access to food to be guaranteed. Economic accessibility means that food must be affordable. Individuals should be able to afford food for an adequate diet without compromising on any other basic needs, such as school fees, medicines, or rent. Physical accessibility means that food should be accessible to all, including to

the physically vulnerable, such as children, the sick, persons with disabilities, or the elderly, for whom it may be difficult to go out to get food. *Availability* requires, on the one hand, that food should be available from natural resources either through the production of food, by cultivating land or animal husbandry, or through other means of obtaining food, such as fishing, hunting, or gathering. On the other hand, it means that food should be available for sale in markets and shops. *Adequacy* means that the food must satisfy dietary needs, taking into account the individual's age, living conditions, health, occupation, sex, etc. For example, if children's food does not contain the nutrients necessary for their physical and mental development, it is not adequate. Food should also be safe for human consumption and free from adverse substances, such as contaminants from industrial or agricultural processes, including residues from pesticides, hormones, or veterinary drugs. Adequate food should also be culturally acceptable.

General Comment No. 12 also contributed to a better understanding of the obligations of states to *respect*, *protect*, and *fulfill* the right to food (following the typology developed by Asbjørn Eide) and of the responsibilities of third parties with respect to the right to food. The obligation to *respect* peoples' existing access to food (be it through agriculture, fishing, husbandry, or purchase) requires states not to interfere with the means by which people acquire food. This obligation requires that states look at the impact of legislation, regulation, and government action on how people procure food. The obligation to *protect* the right to food requires states to adopt measures to ensure that enterprises or individuals do not deprive individuals of their access to adequate food. This obligation provides that states regulate non-state actors and create entities to monitor and investigate third parties and that institutions are in place to ensure that those whose rights have been violated are able to seek remedies. The obligation to *fulfill* the right to food has two elements: provide and facilitate. The obligation to *fulfill* (provide) requires that states meet the right to food directly when individuals or groups are unable to meet their food needs by their own

means, for example, through food stamps, social security schemes, or food aid delivery. The obligation to *fulfill* (facilitate) requires states to be proactive in creating activities aiming at reinforcing people's access to and utilization of resources and means to ensure their livelihood in the future, for example, through reinvestment in small-scale farming or employment creation.

The right to food, as described in the General Comment 12, is to be achieved progressively. The concept of *progressive realization* seeks to take into account the potentially costly implications of some state obligations, especially of the obligation to protect and the obligation to fulfill, in particular for Southern countries. Yet, states are required to take steps to achieve the full realization of the right to food *to the maximum of available resources* and to seek international assistance in case they lack the resources they need. They must also immediately prohibit discrimination in access to food and to the related resources (on the basis of race, color, sex, language, age, religion, political or other opinion, national or social origin, property, birth, disability, or other status) and adopt measures to eradicate discrimination on these grounds.

In addition to the *substantial* requirements described above, the right to food places a number of *procedural* requirements on states. States are required to ensure that people can adequately participate in government decision-making, from policy formulation to lawmaking down to administrative acts. For example, when negotiating trade and investment agreements, states should conduct *human rights impact assessments* to ensure that the agreements they conclude are consistent with their obligations under international human rights instruments (De Schutter 2011). The procedural principles at the heart of the right to food – participation, accountability, nondiscrimination, transparency, human dignity, empowerment, and rule of law – have been summarized by the FAO with the acronym PANTHER (FAO Right to Food Team 2013).

The Voluntary Guidelines to Support the Progressive Realization of the Right to Adequate Food in the Context of National Food Security were adopted in 2004 by the 187 Member States

of the General Council of the FAO. The Guidelines were celebrated for bringing an economic and social right “from formal recognition at the international level to full engagement by governments and international organizations” and from principle into “proposals for concrete action” (Rae et al. 2007, 457). The history of the FAO Voluntary Guidelines is considered a success story by many observers for the importance of civil society’s contribution to the process and content and for managing to gather the necessary impetus to make it happen. Contrary to the elaboration of General Comment 12, the content of the Guidelines was discussed in an intergovernmental process rather than by experts alone. The negotiation process paved the way for the increased involvement of CSOs in the policy elaboration work of the FAO and is said to have had a lasting influence on the way FAO interacts with civil society (Rae et al. 2007, 457). It has also facilitated the inclusion of CSOs as active stakeholders in the reformed Committee on World Food Security (McKeon 2011).

Monitoring and Implementing the Right to Food

Following the adoption of the Voluntary Guidelines, significant progress has been made in the implementation of the human right to adequate food at the country level. Advances are patent in five areas: the integration of the right to food in constitutions, the adoption of legal and constitutional frameworks, the development of national strategies based on the right to food, the use of the right to food in courts, and the design of institutions charged with ensuring progress toward the realization of the right to food (De Schutter 2010, 2012a, b). In addition, country assessments conducted either by the UN Special Rapporteur on the right to food (called official missions) or by nongovernmental organizations have done a lot to demonstrate that the right to food requires attention to be paid to multiple policy areas in order to be fulfilled. The right to food approach to hunger and food insecurity is increasingly associated with interministerial and cross-sectoral coordination as

well as with the setting of clear targets and adequate budget allocations.

At the international level, a Right to Food Unit (now Right to Food Team) was set up within FAO with the aim to support the implementation of the right to food. The Unit develops methods and instruments to assist stakeholders in the implementation of the right to food and information and training materials on the right to food. It is also supposed to work toward integrating the right to food into FAO’s work. The UN Special Rapporteur on the right to food, a new institution established in 2000, also contributes significantly to the implementation of the right to food at the global level. Appointed by the Commission on Human Rights, the Special Rapporteur belongs to the UN Special Procedures system. The mandate of the Special Rapporteur is to establish cooperation with governments; intergovernmental organizations, in particular the FAO; and nongovernmental organizations and to make appropriate recommendations on the realization of the right to food as well as to identify emerging issues related to the right to food worldwide.

In parallel, developments have taken place in the area of monitoring efforts undertaken by states to meet their human rights obligations. The Committee on Economic, Social and Cultural Rights (CESCR) developed indicators to address the problems of how to measure effectively the degree of rights realization. Three kinds of indicators were elaborated with the support of academics and specialized NGOs: *structural indicators* (measure whether or not appropriate legal, regulatory, and institutional structures are in place), *process indicators* (assess whether laws, policies, and programs are in place to implement specific rights), and *outcome indicators* (evaluate the results achieved) (FAO Right to Food Unit 2008, Vol. II, 18).

Progress has also been made, in recent years, in better understanding the extraterritorial implications of the right to food. Indeed, the advent of economic globalization has meant that states and other global actors exert considerable influence on the realization of economic, social, and cultural rights across the world. In 2011, in an attempt to address this situation, a group of experts in

international law adopted the “Maastricht Principles on Extraterritorial Obligations of States in the area of Economic, Social and Cultural Rights.” The *extraterritorial obligations* of states broadly fall under two categories: the obligations relating to the acts and omissions of a state, within or beyond its territory, that have effects on the enjoyment of human rights outside of that state’s territory and the obligations of a global character that are set out in the Charter of the United Nations and human rights instruments to take action, separately and jointly through international cooperation, to realize human rights universally (ETO Consortium 2011, paragr. 8).

Finally, in December 2008, an “Optional Protocol to the International Covenant on Economic, Social and Cultural Rights” (OP-ICESCR) was adopted, following intense advocacy by a network of international civil society organizations, including, among others, the Amnesty International, the Centre on Housing Rights and Evictions (COHRE), the FoodFirst Information and Action Network (FIAN), the International Commission of Jurists (ICJ), the International Federation for Human Rights (FIDH), and the International Network for Economic, Social and Cultural Rights (ESCR-Net). The OP-ICESCR allows victims of violations of ESCR to present complaints before a United Nations body against a state that violates the obligations established in the Covenant, if the state has ratified the Optional Protocol. Following ratification by 10 states, the Optional Protocol will come into force on May 5, 2013.

Despite the development of new legal frameworks, institutions, and mechanisms to monitor the implementation of the right to food, at both the national and international levels, violations of the right to food remain a daily reality. Despite decades of the growing global wealth, poverty and food insecurity remain pervasive, and socioeconomic and gender inequalities endure across the world. Individuals and communities face the continuing deprivation and denial of access to essential lands, resources, goods, and services by state and non-state actors alike. The full realization of the right to food will require structural changes both at the national and international levels. At the national level, the elaboration of

participatory *right to food strategies*, ensuring policy coherence across sectors, could go a long way toward addressing the specific needs of the most vulnerable segments of the population, either in urban settings or in the countryside. At the international level, an alternative global governance framework for food and agriculture will need to be developed as an alternative to the still prevailing Washington consensus (De Schutter 2009) to ensure that international trade, finance, and investment rules, as well as global development and cooperation policies, effectively contribute to the realization of human rights for all. The recent reform of the Committee on World Food Security (CFS) could be promising in that regard, in that the reformed CFS provides a new space for the meaningful participation of non-state actors in intergovernmental decision-making processes and new ways of setting international norms.

Summary

The right to food is an internationally recognized human right. The normative elaboration of the right to food was achieved, in the last decades, mostly through interactions between academics and human rights experts at the UN level. The normative content of the right to food is now well defined, and so are the obligations that fall on states when it comes to its realization. The right to food now faces challenges of enforcement and implementation.

[Taste and distaste and food](#); [Vegetarian diet](#); [You are what you eat](#)

Introduction

Throughout his work, Jean Jacques Rousseau is concerned with food and diet. His writings suggest that a wholesome diet leads to a wholesome character and that good taste is a matter of purity and simplicity in both diet and actions. A vegetarian himself, he often advocates a vegetarian diet, especially for children.

Civilization Is the Result of Moving from Meat Eating to Grain Eating

In both *A Discourse on Inequality* (Rousseau 1984) and *On the Origin of Languages* (Rousseau 1966), Rousseau describes “civilized man” as the result of the evolution from savage hunter, through barbaric herdsman, to civilized farmer. The different social organizations described by Rousseau correspond to “man’s” livelihood and, more specifically, to his relation to what he eats: “The savage human is a hunter, the barbarian is a herdsman, and civil man is a tiller of the soil” (Rousseau 1966, p. 38). Rousseau describes the savage men as “terrible meat eaters” who hunt and kill animals (Rousseau 1966, p. 35); while barbaric herdsman are a step forward because they cultivate and domesticate animals for food, civilized men have learned to use animals both directly and indirectly for food through harvesting

crops using animals to till the soil. The movement from spontaneity to convention, from savage to civilized, is a movement away from chance and toward necessity.

The Birth of Love and Nations Is Related to Food

Even Rousseau's most romantic description of the birth of love, and thereby of nations, is related to consumption: the girls come to the watering hole to fetch water and the boys to water their herds. "Feet skipped with joy, earnest gestures no longer sufficed, being accompanied by an impassioned voice; pleasure and desire mingled and were felt together. There at last was the true cradle of nations: from the pure crystal of the fountains flow the first fires of love" (Rousseau 1966, p. 45). Language is not only from, but also for, passion; "stirring the heart and inflaming the passions takes words" (Rousseau 1966, p. 8). Language, then, becomes part of a mating ritual that gives birth to love. But, the fire of love is not far from the fire necessary to cook the cattle that the boys are herding; and the stirring of hearts is born from the stirring of pots into which the girls have poured their bounty. The beginnings of love and therefore of nations were the result of the combination of water and cattle, eventually boiling together in the cauldron of domestic bliss.

On Rousseau's account, human society is organized according to providence in accordance with its provisions. In other words, "we are what we eat." Savages eat wild animals and they are wild. Herdsmen eat domestic animals, so even if they are still barbaric and their manners crude, they have been domesticated. Civilized men eat cultivated grain and through their cultivation of the soil, *they* become cultivated: "Concerning agriculture, which is slower to come into being: it is connected to all the arts; it leads to property, government, and laws, and gradually to the misery and crime that are inseparable for our species from the knowledge of good and evil" (Rousseau 1966, p. 37).

Not only are the human and humanity constituted in relation to what they eat, but also men constitute themselves as humans by using animals directly and indirectly for food, by eating animals. At one point, Rousseau suggests that humans are

separated from animals through their ability to make and use fire, but it turns out that fire is motivated by the need to cook meat. Again, the ability to cook other animals and eat them becomes a sign of our distinctiveness and intelligence. In a footnote, Rousseau remarks "...no one would say that any beast, wild or domestic, has acquired the skill to make a fire in the same way that we do. Thus these rational beings who are said to have formed a short-lived society before human, still did not reach a level of intelligence at which they were able to strike a few sparks from a flint to make a fire, or even to preserve whatever random fires they might come across" (Rousseau 1966, p. 41). Here, the ability to make fire is seen as a sign of intelligence and of man's capacity for reason. Yet, in the paragraph to which this footnote is appended, Rousseau claims that the stomach and intestines of human are not made to digest raw meat and that "with the possible single exception of the Eskimos. . . even savages cook their meat" (Rousseau 1966, p. 41). So, fire is not a sign of intelligence as much as a natural necessity given the constitution of man's gut. Rousseau goes on to say that people gather around fire because the flames are useful and pleasing "and on this simple hearth burns the sacred fire that provokes in the depths of the heart the first feeling of humanity" (Rousseau 1966, p. 41). Humanity, then, is born out of man's *need* to cook and eat animals (even while for Rousseau civilization is born out of human overcoming the need to eat animals). In this passage, man's intellectual superiority over animals appears as a consequence of man's *need* to cook his meat. Again, the providence of nature gives human a necessary advantage over animals when it comes to fire; and the proof of this advantage is that men can kill, cook, and eat animals.

Man Is an Omnivore, Which Makes Him Superior to Other Animals

Man also has the advantage that, unlike animals, he is not a picky eater. Because men will eat anything, they are more adept at survival than other animals. Again, Rousseau links man's distinctiveness to his digestive track and eating habits, which, it turns out, he appropriates from

other animals: “Man dispersed among the beasts, would observe and imitate their activities and so assimilate their instincts, with this added advantage that while every other species has only its own instinct, human, having perhaps none which is peculiar to himself, appropriates every instinct, and by nourishing himself equally well on most of the various foods the other animals divide among themselves, he finds his sustenance more easily than do any of the others” (Rousseau 1984, pp. 81–82). Men *learn what and how* to eat from animals; through this animal pedagogy, they are able to imitate animals and assimilate animal instincts. And, while each animal eats only what is natural to it, by imitating all of them, men eat everything.

In fact, Rousseau’s argument for man’s freedom against animal instinct hinges on his observation that men will eat everything while animals have more restrictive diets. It is noteworthy that it is not animal in general or animality that teaches men what is edible; rather, the assortment of animals in their midst teaches them about different food stuffs that may be eaten. It is only by learning lessons from various animals that men develop the multifarious diet that gives them the edge, through which men become human. Men eat/assimilate animals both literally as food and figuratively insofar as men ape animals’ eating habits.

In his discourse on inequality, this argument takes many forms involving diet and food, including the fact that unlike other animals, human does not serve as food for another (Rousseau 1984, p. 83); he is distinctive in that he eats but is not eaten by other animals. Rousseau also cites differences in human and animal infancies and maternal feeding practices as reasons for human sociality – human mothers are able to carry their young to feed them at all times while other animals cannot (Rousseau 1984, p. 84). Ultimately, though, human is distinguished from animals through his “free will,” which is based on the freedom to eat anything while “a pigeon would die of hunger beside a dish filled with choice meats and a cat beside a pile of fruits or grain, even though either could very well nourish itself with the foods it disdains, if only it were informed by nature to try them” (Rousseau 1984, p. 87).

Man’s resistance to “the call of nature” is the result of his ability to appropriate instincts from a variety of other animals that allows him to eat indiscriminately among their foodstuffs. So, it is man’s assimilation of animal instinct that enables him to transcend instinct, which amounts to the freedom to eat as he will, which he learns from animals (Rousseau 1984, p. 87).

The Virtues of Vegetarianism

Given Rousseau’s stance on eating meat, the sign of more civilized men should not be that they can eat anything but rather that they can choose what they eat. In *Émile*, Rousseau repeatedly condemns meat eating, especially in children and nursing mothers. He claims that children fed a vegetarian diet are less likely to get worms and colic because farinaceous foods produce more blood than meat and they are less likely to rot (Rousseau 2003, p. 28). He extols the virtues of milk, which (along with cheese, judging by his recollections in *Confessions*) is one of his favorite foods; he proposes that “Milk, although manufactured in the body of an animal, is a vegetable substance; this is shown by analysis; it readily turns acid, and far from showing traces of any volatile alkali like animal matter, it gives a neutral salt like plants” (Rousseau 2003, p. 29). And as further proof of the benefits of a vegetarian diet, he says that the milk of herbivores is sweeter than that of carnivores. He argues that a diet of vegetables is not only healthier than a diet of meat but also more natural. As “proof” that eating meat is not natural, he claims that children do not like to eat meat (Rousseau 2003, p. 140). And, as he does so often, he points to the behavior of other animals to demonstrate what is natural to human animals: “Women eat bread, vegetables, and dairy produce; female dogs and cats do the same; the she-wolves eat grass. This supplies vegetable juices to their milk. There are still those species which are unable to eat anything but flesh, if such there are, which I very much doubt” (Rousseau 2003, p. 29). That all animals eat vegetables is proof that it is natural to do so. As we have seen, although meat eating is natural to savage human, the more civilized man becomes, the greater the distance from his “prey.” Or, conversely, the more human

distances himself from the animals that he eats, the more civilized he becomes.

Recall that the third stage of man's development, as Rousseau describes it, is plowman who cultivates grain instead of cattle. At this point, there are two possible directions for human: he can continue to eat meat but now distance himself from the killing of his animal food in order to disavow his killing, or he can choose not to eat meat. Grain becomes either a means to feed animals for man's consumption or a means by which human makes the transition from carnivore to herbivore. Rousseau begins by arguing that a vegetarian diet is healthier, then he claims that it is more natural, and finally, he makes a connection between taste and morality: vegetarianism is a moral choice that is evidence of man's freedom not to eat meat. Unlike other carnivores, human can choose to become an herbivore. Unlike animals, in humans, eating gives rise to moral inclinations. For Rousseau, this is another reason why the child's diet is important. Given his statements on taste, in a paradoxical sort of way, animals should have a better moral sensibility than humans.

The Beginnings of Private Property Is Also Related to Food

Rousseau maintains that "the first cake to be eaten was the communion of the human race" (Rousseau 1966, p. 35). It is cake that brings men together; cake is the basis of human society. No other animal can make a cake, which for Rousseau is the result of the cultivation of fields, the beginning of all art and artistry (never mind that Rousseau does not talk about the making, but the eating, of cake, ignoring the fact that other animals can eat cake and ignoring the fact that even cavemen painted pictures). Sowing for harvest requires ownership of land, tools, foresight, and community, all of which are lacking in hunters or shepherds (Rousseau 1966, pp. 33–34). Although animals are used for farming and many of the early tools for tilling the soil required oxen and horses, Rousseau imagines the civilized man as a grain eater who begins to separate himself from the animals that he consumes, which are raised and slaughtered elsewhere and for which he trades his harvest. In this regard, distance

between human and his animal-eating is a sign of civilization. He no longer hunts wild animals or slaughters his domestic animals; now, he uses animals to produce crops that he can exchange for animals once they have become meat and other commodities. This is the beginning of property, which Rousseau identifies with the beginning of dependence, bondage, servitude, and the inequality of men (e.g., Rousseau 1984, pp. 105–106). We could say that for Rousseau as human disavows his dependence upon animals and his diet of animals by shielding himself from their production for food, by turning them into commodities – meat instead of animals – he becomes more civilized (and more corrupt). Human society, then, is based on the double sacrifice of animals: first the killing of animals for food and then the concealing of that killing so that human can continue to eat animals without guilt. Rousseau's text seems to argue that vegetarianism might be a sign of higher development.

Rousseau's writings suggest that choosing to eat cake instead of eating animals is a sign of the higher evolution of natural human. Rousseau also identifies the inequality of men in society with differences between foods that did not exist with natural or primitive human: "Now if we compare the prodigious diversity of upbringings and of ways of life which prevail among the different classes in the civil state with the simplicity and uniformity of animal and savage life, *where everyone eats the same foods*, lives in the same style and does exactly the same things, it will be understood how much less the difference between human and man must be in the state of nature than it is in society. . . ." (my emphasis, Rousseau 1984, p. 105). Eating the same foods is the first characteristic of the equality among animals, including savage men. Like the differences between animals and human, differences between men are evidenced in the differences between what they eat. Again, freedom is described as the freedom to eat what one will, to eat freely from a variety of foods, while servitude (whether it is to instincts in the case of animals or to other men in the case of humans) is evidenced in not having a choice about what one eats.

Rousseau compares the accumulation of slaves as property to the collection of cattle. And, he says that the rich are like "ravenous wolves, which,

having once tasted human flesh, refuse all other nourishment and desire thenceforth only to devour men” (Rousseau 1984, p. 120). It should not be surprising, then, that for Rousseau, man’s relation with animals sets the stage for his relation with humans – we mistreat each other because we mistreat animals. For example, collecting and owning cattle prepare human to collect and own human slaves (Rousseau 1984, p. 131). And, from hunting and killing animals, human learns war and conquest; “war and its conquests is just a kind of manhunt” (Rousseau 1966, p. 36). Herding cattle teaches men to herd men; hunting wild animals teaches men to hunt men. Man’s cruelty to other men echoes his cruelty to animals. The rich can be “like wolves” and “devour” men only because men first prey on wolves. Again, Rousseau claims that man’s character is formed in relation to what and how he eats: flesh eaters are cruel while flower eaters are gentle (Rousseau 2003, pp. 140–141). He asserts that “all savages are cruel, and it is not their customs that tend in this direction; their cruelty is the result of their food. They go to war as to the chase, and treat men as they would treat bears. . . Great criminals prepare themselves for murder by drinking blood” (Rousseau 2003, pp. 140–141).

Moral Tastes Develop from Tastes in Food

Arguing for a vegetarian diet, in *Émile*, Rousseau maintains that it is not only for health’s sake that children should avoid eating meat but also for their characters (Rousseau 2003, p. 140). He argues that eating flesh begins and ends in cruelty. Quoting Plutarch, he gives a forceful account of the barbarity of killing and eating animals (Rousseau 2003, p. 141). Barbarity toward animals begets barbarity toward fellow humans. Rousseau’s analysis suggests that hunting and killing animals are training grounds for hunting and killing men; war is a natural outgrowth or at least a side effect of slaying animals. Flesh eaters make war and war-makers are hunters.

For Rousseau, when it comes to ethics or morality, the process of assimilation is not just metaphorical but also literal. In *Émile*, he describes in detail the proper diet to nourish both body and mind. There, he recommends a vegetarian diet, especially for children, who he says are healthier when they do

not eat meat (Rousseau 2003, p. 28). As we have seen, he extols the virtues of milk, particularly the milk of herbivores, which he says is sweeter than that of carnivores (Rousseau 2003, p. 29). Even the curds in milk are healthy because they nourish by becoming solid and therefore do not merely pass away as liquid (Rousseau 2003, p. 29). Rousseau prefers simple, easily palatable, pure foods, such as milk and cheese. But food is much more than nourishment for the body. In *Émile*, food is also a pedagogical tool used to “lead children through the mouth” (male children are more susceptible to these techniques than female children, who are “more eager for adornment than for food”) (Rousseau 2003, p. 139, cf. 396). Cakes are used to teach children the value of industriousness and exercise (Rousseau 2003, p. 127). And ice cream becomes a tutorial in coldness (Rousseau 2003, p. 199); and finding lunch is the goal of astronomy lessons (Rousseau 2003, p. 173).

Indeed, for Rousseau, what and how one eats are signs of the strength of one’s mind. He says “gluttony is the vice of feeble minds. The gourmand has his brains in his palate, he can do nothing but eat; he is so stupid and incapable that the table is the only place for him, and dishes are the only things he knows anything about” (Rousseau 2003, p. 139). As he describes it, we should attend to good eating habits not only for the sake of our bodies but also for the sake of our minds. This is because of all of our senses, taste (*goût*) affects us most in that “it concerns us more nearly to judge aright of what will actually become part of ourselves, than of that which will merely form part of our environment” (Rousseau 2003, p. 138). Although he maintains that matters of taste (*goût*) – both physical tastes and aesthetic tastes – are physical and material, nevertheless, they both affect the mind and character (e.g., meat eaters are cruel) and can be symptoms of a weak mind and character (e.g., gourmards are stupid). It is interesting to note that Rousseau uses the same word “*goût*” for taste in both the physical and the moral sense. We need to concern ourselves with good taste but not necessarily with what tastes good. We can (and should) train our tastes to appreciate purity and wholesome “goods.” Moreover, he suggests that simple tastes are closer to nature and therefore not just good to eat but morally good. The

sensation of taste gives way to, and becomes a sign of, moral taste.

Although Rousseau says that the laws of moral taste and physical taste differ, he repeatedly associates pure and wholesome food with pure and wholesome morals (cf. Rousseau 2003, pp. 365, 139, 368). Both moral taste and physical taste are good when they are close to nature, while both become corrupt the further they move away from nature. In this romantic view, nature is innocent, pure, wholesome, and good; and it is corrupted only by man's attempts to change it. Rousseau's writing suggests that if we assimilate what is pure, wholesome, and good, then we become pure, wholesome, and good: we are what we eat because the sense of taste affects us more than other senses insofar as food becomes part of ourselves.

A healthy and pure lifestyle satisfies itself with a healthy and pure diet: "There are no such cooks in the world as mirth, rural pursuits, and merry games; and the finest made dishes are quite ridiculous in the eyes of people who have been on foot since early dawn" (2003, p. 379). In Rousseau's romantic vision, exercise and picnics outdoors beneath a tree or alongside a river are the greatest pleasures because they are the purest, which is to say the closest to nature: "our meals will be served without regard to order or elegance; we shall make our dining-room anywhere, in the garden, on a boat, beneath a tree ..." (Rousseau 2003, p. 379). For Rousseau, taking pleasure in such simplicity is evidence of a pure heart.

When Rousseau turns his attention from physical tastes or food to aesthetic tastes, he once again insists that *Émile* develops simple tastes "in order to keep his taste pure and wholesome" (Rousseau 2003 p. 368). Even as he maintains that bodily tastes and moral tastes are two separate realms, he continues to develop the analogy between them: aesthetic tastes are moral only if they are natural, pure, and wholesome, while food that is natural, pure, and wholesome nourishes a good body and a good mind or soul. In the end, one of the central lessons of *Émile* is that the natural human should develop a taste for pure, simple, and wholesome nourishment for *both* body and soul. In order to be

pure, however, *Émile*'s simple pleasures must be shared with others. Many of Rousseau's lessons are designed to teach the value of generosity: "If you have pleasure without pain let there be no monopoly; the more you leave it free to everybody, the *purer* will be your own enjoyment ... real pleasures are those which we share with the crowd; we lose what we try to keep to ourselves alone" (my emphasis, Rousseau 2003, pp. 381–382). Here, Rousseau is discussing poachers and "ordinary sportsman, who on a good horse, with twenty guns ready for them, merely take one gun after another, and shoot and kill everything that comes their way, without skill, without glory, and almost without exercise" (Rousseau 2003, pp. 381–382). His ideal estate is wild and without fences where game is not preserved and therefore not poached or hunted without strenuous efforts. The way that one hunts animals becomes a criterion for good taste. Hunting and eating will be truly pleasurable – pure pleasures – only if they are close to nature and simple and one has to work for them. Only then will one truly appreciate them without squandering them and without arrogance. The "good" hunter hunts for exercise and food to share and not for trophies or sport alone.

"Good taste," then, also requires that *Émile* gives up illusions of property or ownership. His estate will have no borders to keep animals in or to keep poachers out. He will share his wealth with others because only then will it bring him pleasure – a lesson that he has taken to heart. *Émile* knows that "with health and daily bread we are rich enough" and that wealth "cannot buy you pleasure"; and because "his heart is purer and more healthy...he will feel it more strongly" (Rousseau 2003, p. 383).

Summary

So, for Rousseau, a pure and healthy heart is more committed to the good life, which he describes as simple and natural, without pretense or property. Conversely, the good life produces a good heart, both physically and morally. The good is related to tastes, both in

food and in pleasures. Moral tastes and bodily tastes, then, are intimately connected. If we eat good food, we become good people.

Introduction

Saving seeds is an ancient and universal practice that has both grounded and propelled agriculture for millennia. The widespread transition from “hunter-gatherer” to “agriculturalist” among humans – dated these days at 12,000 years ago – centered on the domestication of edible wild plants into cultivated crops: in short, the selecting and saving of seed with desired traits so as to replant later and/or elsewhere. The practice of saving seeds has always entailed complex social and cultural dimensions, as seeds have physical as well as metaphysical currency in many agrarian societies. The people in a community who held the responsibility of saving seeds – often women, often elders – were endowed with a critical social obligation and function. This is still the case in

traditionally agrarian communities across the continents. As agriculture became more industrialized in the twentieth century, the practice of seed saving receded in import; more growers turned to annually purchased seed stock (be it hybrid, or later, genetically modified). More recently, however, for a variety of reasons, the ethical dimensions of seed saving have reemerged, and these ethical dimensions have taken on an explicitly political framework.

This brief introduction to the rich topic of seed saving begins with a biological overview of the practice. It then moves to an historical survey of major twentieth-century changes in agriculture, emphasizing in particular ethical issues regarding the evolution of intellectual property rights, the widespread decline in agricultural biodiversity, and the ex and in situ attempts to conserve this cultivated diversity. (Of note, this essay has a US focus, but the basic phenomenon are not unique to the United States.) The essay ends with a discussion of ethical debates regarding the politics of seeds and their saving.

Biological Basics

Seeds are mobile, self-sustaining packages; they carry all enzymes required for the embryo to convert the stored nutrients to tissue-building sustenance. They also carry all the genetic information of the plant, including genetic traits that were expressed in previous generations as well as genetic potential to express other traits in response to new abiotic contexts and pressures. This genetic blueprint is encoded in the deoxyribonucleic acid (DNA) molecules, which determine the genetic traits therein and how and when they will be actualized.

Botanically speaking, a seed is a ripened and fertilized ovule that contains the plant in embryonic form as well as nutrients for the embryo during its indefinite dormancy. This embryo and stored nutrients are encased in a seed coat. Yet, many seed savers select, save, and sow parts of the plant that are technically fruits, though they act like seeds – such as corn kernels. All seeds contain one or more cotyledons or folded, rudimentary

leaves, which themselves contain stored fat, protein, and carbohydrates. The cotyledon(s) is partially wrapped around the tiny leaf bud. Next to the cotyledon(s) and tiny leaf bud rest both a rudimentary stem and a root tip, which – when the seed germinates – extends to become the plant's first root. If a seed contains two cotyledons, it is called a dicot; if one, a monocot. Squash, beans, cucumbers, tomatoes, celery, cabbage, and most other vegetables that bear seed are dicots and send forth two small seed leaves upon germination. Onions and garlic are monocots, and, once germinated, send forth a single spear-like blade of grass. Also, most grain crops in the grass family (*Gramineae*) – including corn, wheat, buckwheat, rye, amaranth, quinoa, rice, and other cereal crops – have one cotyledon and are thus monocots (Bubel 1988).

In some seeds, the stored nutrients are not contained in the cotyledon, but in the endosperm, the layer of starchy seed flesh that surrounds the embryo. For many major grain crops, the endosperm nourishes the embryo – but it also feeds the human or animal eating the seed as food, as in the case of corn, wheat, rye, buckwheat, and other cereal grains. Endosperm results from the fertilization of the plant: when a male gamete fuses with a pair of female nuclei in the embryo sac, endosperm is produced. It consists of three layers: the aleurone, which breaks down starch; the transfer layer, which absorbs nutrients for the plant itself; and the larger, internal layer, which provides the bulk of the starch.

The act of saving seed depends upon the phenomenon of dormancy, during which the seed produces chemicals that inhibit germination. Seeds are self-sufficient and self-protected during dormancy – which can last for days or millennia. The seed coat provides a water-resistant, impermeable physical protection to the seed embryo and nutrients inside. Seed coats also protect against parasites, minor injuries, and, to some degree, high or low temperatures. When dormant, the seed's metabolic function operates slowly and efficiently, drawing nutrients from the cotyledon or endosperm at a significantly lower rate than after germination.

Dormancy culminates with the pivotal moment of germination, when a seed awakens to begin

taking root and sending forth cotyledon. The first sign of germination is absorption of water, which activates an enzyme that speeds respiration and catalyzes plant cells to duplicate. This increases the size of the embryo, which ultimately must break out of its seed coat and unfurl itself. The root tip extends downward to anchor the growing plant. The mobile stage of the plant ends here, as it takes root and begins its place-bound life. Besides spatial fixity and balance, the root tip serves to absorb water and nutrients from the soil, as that by now, the embryo needs more than what its seed content could provide.

A seed germinates depending on surrounding conditions, from temperature to moisture, to light, to oxygen supply. A viable seed might not germinate if the conditions are unfavorable. Some seeds need to be coaxed out of their protective dormancy at times, such as lettuces; gardeners sometimes use fluorescent plant lights to convince a lettuce seed to emerge into a lettuce plant. Some wildflower growers “scarify” the seed coats of certain wild legumes to encourage the seed to begin germination. Most wild plants and wildflowers require a period of dormancy before they will germinate, while cultivated garden flowers usually do not. To test viability, growers run germination tests on their stored and saved seed; the percentage that sprouts indicate the overall viability rates of the seed. The grower can continue exchanging, storing, and/or sowing the seed.

Once sown, the seed germinates and grows, developing into a plant that flowers, becomes pollinated, and bears fruits – and more seeds. Whether self-pollinated or wind-, insect-, or hand-pollinated, the flowering plant produces seed that can be saved. Annual seeds produce seed each year, while perennials do not necessarily, and so must be propagated through cuttings or plant division. Seed savers usually save from more than one plant, so as to avoid inbred stock and to maintain overall genetic diversity and vigor. In most plants, seeds are gathered at the end of the growing season to make sure the seed has developed a sufficiently mature embryo and endosperm. Timing is key, since growers must gather seed at the right stage of seed development and at the right temperature and moisture level:

seeds that are too wet could mold. Fleshy fruits, such as melon, cucumbers, tomatoes, eggplants, and peppers, need to be slightly overripe before harvesting them for seed saving. If the fruit begins to rot, excessive heat from decomposition could damage the seed. Also, diseased vegetables often pass along pathogens to their offspring. Once harvested, some seeds (peas, snap beans, soybeans) need to be threshed to remove the pods. Saved seeds need a postharvest drying period to allow any accumulated moisture to evaporate (Ashworth and Whealy 2002).

Genetic vigor is determined by parental lines and passed along genetic traits. Physiological vigor depends upon the conditions within which the seeds were formed: temperature, sunlight, moisture levels, and soil nutrient availability. The vigor of a seed cannot be improved with correct storage, but it can be hindered with poor storage. Seeds should be kept cool and dry, since heat and moisture activate premature internal embryonic metabolism. Also, cold and dry conditions inhibit growth of bacteria, fungus, mold, diseases, and insects. A note of caution given by seed savers far and wide is to avoid planting all of one seed variety at one planting. Saved seeds are valuable for their productive and reproductive capacity; they are saved for present and future plantings and are not all to be replanted in one season in case of crop failure.

Agricultural Changes: Historical Politics of Seeds and Intellectual Property Rights

Throughout history, seed saving has served as a chief means of obtaining seed. Even growers with access to seed markets and networks would save the best seeds from their own fields to replant later and/or exchange with or sell to other growers. Yet, during the past century, the propensity toward seed saving has decreased in the Global North and even in the Global South, as formal seed markets have grown and as seed types – be they hybrid or transgenic – have prohibited their saving.

This transition toward laboratory-based breeding drew in large part upon the early twentieth-century applications of mid-nineteenth-century

hereditary discoveries of Gregor Mendel. The scientific field of genetics developed rapidly throughout the twentieth century, transforming agriculture in the process. In the USA, public and “land-grant” universities explored and developed hybrid varieties of corn and wheat – among other crops. These seeds were unusually productive during the first generation (F1) after cross parent lines. But due to intensive inbreeding, these “high-yield” hybrids did not produce a productive – or even reliable – second generation of plants (F2). Therefore, biologically speaking, they were the first single-season, annually purchased seed input. The hybrids generated high yields per hectare of commodity crops; they also generated considerable income for the private industries that took an increasingly share of research and development from public institutions. American Seed Trade Association, formed in 1883, lobbied, successfully, to end the US government’s decades-long practice of distributing free seed to growers so as to encourage their field-breeding experimentation. By the 1930s, the private seed industry had established its market and begun a century of exponential consolidation and growth (Kloppenborg 1988).

The “vigor” of hybrid seeds – along with their affiliated spate of irrigation, chemical fertilizer, and chemical pesticide inputs – led to unprecedented yield per hectare increases in commodity crops during the middle of the twentieth century. This “Green Revolution” produced massive harvests of cereal grains for the global market but heralded notorious ecological and social effects, ranging from massive biodiversity loss, soil erosion, and water pollution to consolidated land tenure and input companies. Where these profound agricultural changes took root, the practice of seed saving moved to the margins.

All the while, seeds – and the genes therein – became subsumed within a growing network of intellectual property legislation. The 1930 US Plant Protection Act helped usher in this new era of seed breeding by establishing patent systems for asexually reproduced plants (be they grafted or cloned). European law followed suit with the *Union internationale pour la protection des*

obtentions végétales (UPOV) in 1961, which established plant breeders’ rights. The 1970 US Plant Variety Protection Act (PVPA) extended this framework by granting certificates of protection for sexually reproduced crops – those reproduced through seed. The 1970 PVPA clarified that farmers would maintain the right to save seed, but this exemption was repealed by congress in 1994. The UPOV maintained a corresponding exemption provision – until 1991 – when it deferred the right to save seed to national discretion and dramatically increased plant breeders’ rights (Aoki 2008).

Then, in 1980, the US Supreme Court decided the landmark case *Diamond v. Chakrabarty*, which held that people or companies could obtain utility patents on living organisms that they had genetically altered themselves. Subsequent lawsuits upheld this expansion of proprietary germplasm commodification. All the while, advances in agribiotechnology allowed plant breeders to isolate, extricate, and modify specific gene sequences, creating transgenic seed varieties that were protected by extensive intellectual property policy. Unlike their hybrid counterparts, transgenic seeds reproduce their defining hereditary traits and thus, biologically, can be saved. To protect their investment, plant-breeding industry has lobbied (successfully) to preclude seed saving through intellectual property rights (IPR) regimes. The logic here is that IPR provides incentives for research and innovation and serves as a means of recouping costly investment.

According to US and European patent law, “naturally occurring products” cannot be patented, but if a person or company discovers an “isolated, purified, or altered form” of this naturally occurring product, they can claim a patent on it. Phenotypic and genotypic organism traits thus can be patented if proven to be (1) newly discovered or created, (2) distinct, (3) uniform, and (4) stable. These guidelines were then exported to other regions of the world through the 1994 Agreement on Trade-Related Aspects of Intellectual Property (TRIPS), a key component of the General Agreement on Tariffs and Trade. TRIPS enshrined extensive plant breeders’ rights by requiring that all countries involved in the World

Trade Organization “harmonize” their intellectual property protections through either UPOV, US patent laws, or a corresponding *sui generis* system (Aoki 2008).

This trajectory toward proprietary ownership of germplasm has escaped neither controversy nor contention. Seeds and the genes therein have existed as a worldwide commons for millennia. Global agricultural biodiversity unfolds as seeds travel from field to field, continent to continent, adapting anew with each season. This flow has been appropriated at times for private gain: imperial enterprises sought to collect exotic seed stock from colonized outposts and capitalize upon its valuable new traits. Botanical gardens housed accessions of such exotic varieties, but, in general, germplasm remained commonly held and openly accessed.

By the beginning of the twenty-first century, however, over half of the global commercial seed market is controlled by three agribusiness conglomerates: Monsanto, DuPont, and Syngenta. This unprecedented level of private industry consolidation – accomplished through two decades of intense company mergers and acquisitions – reflects a global political economy of corporate consolidation, but the seed industry has come to embody this concentration – of revenue, resources, access, control, and political leverage. During the rise of agribiotechnologies such as genetically modified seeds, the price of seeds has increased considerably. Meanwhile, food prices spiked in 2008 and have risen subsequently. Moreover, both seed and food prices are subject to financial volatility that has only increased as food has become a more prominent future commodity for financial speculation. Accordingly, growers, advocates, and policy makers have begun to bring the issue of seeds – and seed control – to more mainstream debates.

Agrobiodiversity Decline

As agriculture became increasingly industrialized in the twentieth century and the monocultural mode of production expanded, overall levels of agricultural biodiversity declined. Growers and

plant breeders alike noted the precipitous erosion of crop diversity. The crisis has unfolded across and between all major and minor crop species: during the twentieth century alone, the UN Food and Agriculture Organization (FAO) chronicled a 75% global loss of agrobiodiversity. Tens of thousands of plant species growing in the world are edible, and humankind has cultivated several thousands throughout history for nourishment. Presently, however, only about 150 species are grown for food, according to FAO research, while 30 crops provide over 95% of human consumption, and only three of these (wheat, maize, rice) supply over 60% human foods. Concurrently, each of these three staple crops has become more genetically homogenous. At all known scales of reference, the variety and variability of domesticated foods and their wild relatives are diminishing (Fowler and Mooney 1990).

Though it has not garnered the public attention of other environmental crises – with the lack of charismatic megafauna in the heirloom seed world – the larger ecological emergency of global climate change has brought its importance to the fore (or at least more to the fore than before). The standard international methods for addressing the problem of agrobiodiversity erosion are through *ex situ* (off-site) conservation and storage of seeds, especially through research centers, such as the mega-gene banks of the Consultative Group on International Agricultural Research (CGIAR). The CGIAR began in 1971 as a means of connecting, streamlining, and strengthening the conservation and research capacities of individual International and National Agricultural Research Centers. Working with hundreds of government and civil society organizations around the world – as well as with private industries – this “strategic partnership of diverse donors” supports and coordinates the 15 international centers – 11 of which house mega-gene banks. These banks play an important role in facilitating agricultural researches on and for agricultural biodiversity conservation. Yet, growers, scholars, scientists, indigenous rights activists, and even international agencies have called for increased attention to and support for *in situ* (on-site) cultivation, such as in farmer fields and home gardens.

Despite lip service to small-scale growers and their farming skills, the politics of seeds and genetic conservation continue to favor *ex situ* strategies of collection and preservation. Moreover, increasingly such conservation measures serve and are subservient to certain sectors of agricultural research, such as those recently dominated by private (rather than public) plant breeding. Consequently, this research is usually funded by and oriented toward highly consolidated agribusiness corporations and expressly committed to “improving” seed stock through genetic modifications and subsequent *de rigueur* intellectual property rights.

Subsequently, farmers and sustainable agriculture advocates have become more pointed in their analyses of the political ecology of agrobiodiversity loss and conservation through *ex situ* conservation; they argue that food security is itself fundamentally dependent on viable, resilient, sustainable agriculture, which is itself predicated upon a viable, resilient, and biodiverse crop base: in short, *in situ* agricultural biodiversity. Accordingly, increasing numbers of small-scale growers and agrarian activists, such as those in Via Campesina, have come to argue that food security entails food – and thus seed – “sovereignty” and that the crisis of agrobiodiversity erosion and the methods to address this problem are more than merely ecological.

Though often framed dichotomously, the delineation between *in* and *ex situ* blurs somewhat upon closer inspection. After all, at times, cultivation partakes of both *in* and *ex situ* strategies. Community seed banks gather seed varieties so as to circulate them for wider cultivation in the local community, and home gardens can serve *in situ* needs of semi-subsistence along with *ex situ* objectives of “growing out” seeds for nearby community seed collectives. US-based Seed Savers Exchange serves as an *ex situ* hub for a wide network of *in situ* growers. Nevertheless, efforts that focus solely on *ex situ* means of conservation often belie a different understanding of agrobiodiversity, its conservation, and its value than that of initiatives focusing on *in situ* cultivation as the chief means of reversing, or at least mitigating, its decline.

These debates parallel a broader dispute regarding the commons of plant genetic resources: *ex situ* gene banks conserve this genetic treasury as a “common heritage of humankind,” even as the holdings are subsumed within growing networks of proprietary IPR. Global contestations on the asymmetrical flow of genetic resources from the gene-rich South to the gene-poor North – and the latter’s disproportionate financial benefit – spurred the 1983 International Undertaking on Plant Genetic Resources, wherein countries gathered to safeguard the genetic commons. The Undertaking was not binding, though, and its commons framework was subsequently undermined by the 1992 Convention on Biological Diversity, which upheld *national* sovereignty of respective genetic resources.

The international debates persisted and ultimately led to the 2001 International Treaty on Plant Genetic Resources for Food and Agriculture, which, when implemented in 2004, instigated a Multilateral System of Access and Benefit Sharing, such that (most) gene bank holdings could not be patented – at least not in the form received by the bank itself. Loopholes remain, but the Treaty did highlight and strengthen “Farmers’ Rights,” which formally recognized the critical contribution of farmers to past, present, and future plant genetic resources for food and agriculture. Farmers’ Rights’ proponents advocated for: (1) the right of farmers to grow, breed, sell, and swap open-pollinated and laboratory-bred seeds; (2) open access to seeds and genes kept in *ex situ* collections; (3) established systems of compensation to recompense and encourage *in situ* agricultural biodiversity cultivation; and (4) increased participation of farmers in decision-making policy forums.

Ongoing Tensions: Rising Interest in Seed Saving, Amidst Increased IPR

After generations of systemic devaluation, there has been a resurgence of interest in the act of saving seed. This has emerged on the margins of conventional agriculture for a variety of reasons. Ecologically, seed saving revitalizes cultivated biodiversity and, often, crop wild relatives as

well. Open-pollinated seeds adapt to changing environments and thus constitute a means of cultivating climate-resilient food production. Seed saving usually occurs in gardens and small farms, where growers, over a few seasons, can acquire particularly strong, well-adapted, prolific, high-quality desirable varieties. Seed-saving growers select for ecological resilience as well as for specific agronomic traits (early-germinating, frost-resistant, heat-tolerant varieties with deep roots that survive well on steeper slopes or sandy soil) or culinary attributes (taste, nutrition, storage capacity, cooking preference).

Seed savers make the commitment to keep heirloom varieties alive and adapted for social reasons, finding cultural identity or continuity in a seed line or in the practice of seed saving itself. Seed savers also highlight the social bonds afforded through seed swaps, gardening networks, and agricultural communities. The seemingly innocuous act of seed saving has taken on explicitly political overtones among seed sovereignty initiatives throughout the Americas and the Asian, European, and African countries. Whether they identify their intentions as “seed sovereignty” or not, seed-saving initiatives and networks have emerged in urban and rural areas, across and throughout the continents of the Global South and North. These growers swap, keep, and breed landraces so as to extricate from an increasingly concentrated seed industry that has gained a striking level of political-economic control over germplasm during the last generation.

In addition to political autonomy and cultural regeneration, some have (re)turned to seed saving for health and aesthetic/taste reasons, so as to assure themselves increased access to fresh produce. In urban and rural areas where fresh fruits and vegetables have become prohibitively expensive, growers with access to land might grow from saved seed as a form of bolstered food security. At the other end of the economic spectrum, growers and restaurateurs might opt to cultivate heirloom seeds due to their increased gourmet status. Rise of heirloom strains of vegetables, which can only be perpetuated through saving. Also a grower might decide to save seeds to assure herself seeds that have not been pretreated with herbicide or pesticides.

Amidst these diverse reasons for and forms of seed-saving resurgence, political tensions around the act have only increased. In the USA, for instance, the 2013 Supreme Court case *Vernon Bowman v. Monsanto* brought the controversies of intellectual property and seeds to the highest judicial review. Bowman, a 75-year-old Indiana farmer, was sued by Monsanto for IP infringement; Bowman contested that all he did was purchase and plant soybean from a local grain elevator. The grain elevator was selling undifferentiated grain seed – some of which was trademarked Roundup Ready soy. Dozens of groups filed amicus briefs on behalf of Bowman, alleging that the seed, under the doctrine of “patent exhaustion,” should be free of intellectual property, since Bowman himself did not sign a company technology contract with Monsanto (that would have legally prohibited the saving of the purchased seed). Meanwhile, numerous amicus briefs were filed siding with Monsanto (including many by public and land-grant universities), alleging that self-replicating technologies need to be an exception to patent exhaustion, so as to assure ongoing agribiotechnology investments. The Supreme Court ruled unanimously to uphold indefinite patents on genetically modified seeds. All the while, however, the growing national and international attention to such seed policy has helped bring the complicated and contested politics and ethics of seed saving to light.

Summary

For a wide variety of reasons, the act of saving seed is reemerging as an important and powerful practice. People and communities have elected to begin, continue, or resume seed-saving networks for food security reasons, health and nutrition priorities environmental concerns, cultural identity, social interdependence, and political independence. Meanwhile, controversies have grown recently as intellectual property protection of new agribiotechnologies increases – and as corporate consolidation of the seed industry reaches unprecedented levels. Seed saving has become a political act – even for those who simply wish to

grow a crop from existing seed stock. The ethical dimensions of seed saving encompass larger questions of the commons and its encroachment. The ethical aspects of seed saving also entail questions of food security – and what has come to be known as food and seed “sovereignty” or autonomy. All the while, the extensive knowledge and skills required for effective seed saving have been devalued for generations but, increasingly, are being re-recognized and revalued as critical for cultivating ecologically resilient, bountiful, and diverse agricultural systems.

Introduction

School lunch and gender research examines whether, how, and why eating differs among girls and boys and whether or not women and men are differently involved in feeding students at school. It is a subfield of school food research. The school food literature is concerned with understanding the underlying values and related behaviors associated with food in schools and with analyzing the goals and implementation of school food policy. This entry uses the terms school food, school lunch, and school meals interchangeably to refer to food or nutritional supplements available to students and the related policies governing the purchase, distribution, and consumption of food in and around schools. Publications delved into all possible scenarios for student eating: breakfast, lunch, snacks, supplemental nutrition, and take-home-from-school food staples for the poorest of students. The literature reflected on the experiences of children who

Scape

- [Food and Place](#)

ate food prepared and served from the cafeteria, who received micronutrients distributed by transnational organizations, who brought lunch from home, and older students who left school during designated breaks.

Gender was the most prevalent variable applied in school food research. The term gender was operationalized in two different manners. The most common way to deploy gender to understand the dynamics surrounding school meals was as a headcount of girls and boys in a sample size. Less prevalent in the research was the use of gender to signify socioculturally defined difference that shaped patterns of eating; food choices; feelings toward the self, school, or school performance; and involvement in school meal administration (Robert and McEntarfer 2014). In other words, rather than counting girls and boys, researchers who applied the latter meaning of gender to their analysis examined why girls and boys selected different items to eat or why girls were sent to school when a lunch program was initiated.

Paying attention to gender did not provide explanations for all patterns related to school lunch. Many researchers took account of other identity markers and societal factors in conjunction with gender. These included socioeconomic status (SES), which in the United States was equated with student's access to free or reduced school meals but also was reflected in who brought lunch to school or was able to purchase food during lunchtime. Race and/or ethnicity also was identified in research studies and linked to SES and gender to understand student choices and the physiological impacts of particular feeding programs.

School lunch and gender research grew exponentially over the first decade of the twenty-first century due to four overlapping concerns for the health and well-being of children. The first concern was with rising rates of childhood obesity and type II diabetes. The second concern was with interrogating the purpose of feeding students at school. The third was a concern for understanding the qualitative impact of eating at school on students' well-being or attitudes toward schooling. The fourth is the smallest group of studies and

explores how research on school lunch and gender was constructed. The rest of this entry elaborates these four concerns attending to the analytic schema laid out by Sandler (2011) to critically examine school food or school food research: "who feeds whom, what, how, and for what purpose" (p. 25). Suggestions for further research are included at the end of each subsection.

Health Impacts

Researchers from across academic disciplines are concerned with halting the worldwide epidemic of obesity and type II diabetes in children. The underlying physiological patterns of consumption or who eats (and does not eat) what and with what health outcome are the concern of these investigations. Rates of obesity and type II diabetes continue to increase worldwide across socioeconomic groups. Researchers concerned with understanding why the diseases were on the rise aimed to determine what was eaten at school that may contribute to the epidemics. Most studies observed what girls and boys consumed or recorded in food journals. Caine-Bish and Scheule (2009) examined food preferences of girls and boys across grades to determine what foods might be incorporated into school lunches to improve healthy eating at school. Their study is of importance to this entry because of the findings: girls and boys have different food preferences, and those preferences change across elementary, middle, and high school. Further studies also measured body mass index (BMI) to ascertain who eats what and with what physiological outcomes. However, as Galloway (2007) showed in her examination of rural Canadian girls and boys, overweight and obesity measures were not statistically significant over a 24-h period of recall but differences in energy and nutrient intake could not be ignored. Lopez-Frias et al. (2005) similarly found boys in southern Spain consumed more calories than girls when lunch was consumed at home though not statistically significant. "It is clear that there is a pattern of dietary intake in this sample that produces greater energy and micronutrient intake in boys" (p. 783). Galloway

hypothesized that sociocultural assumptions that favor boys when decisions were made about health-care access, quality of food consumed, and amount of food served may have shaped the differences and urged further research. Studies also examined what parents sent in packed lunches and noted differences between what was sent for girls and boys. Boys were sent more food in general, perhaps reflecting the cultural assumption that boys require more overall calories without regard for the items consumed (Jones et al. 1999). The same study found that fat content of bag lunches (lunches brought from home) correlated with ethnicity and gender but not with socioeconomic status (SES). Future research needs to consider how gender and ethnicity shape what is eaten at school whether brought from home or selected at school. Girls were found to consume more fruits and vegetables than boys, a marker of healthy eating habits (Reynolds et al. 1999). Girls also were found to have more fruits and vegetables sent in packed lunches from home (Brennan et al. 2010). Few studies critiqued why girls and boys consumed different items, leaving many questions about eating behaviors that have an impact on health and the values that shape girls'/boys' choices for future researchers to answer. While not addressing ethical questions, many of the studies that related to school lunch health impacts laid the foundation for future studies to do so.

Why Eat at School?

Whether or not students should be fed at school is not a debated issue: governments around the world will feed students if funds are available (Bundy et al. 2009). In developing or high poverty contexts, school lunch draws boys and girls to school. Pertinent to this study, serving food at school encourages poor families to send their daughters and keeps them coming back. Why students were being fed, what, and for what purpose can be a driving force behind differences in school access. Studies also compared lunches eaten at home with meals available at school. For example, Lopez-Frias et al. (2005) found

students consumed more nutritious foods at school than at home where, they postulated, children influenced what was served more than at school. In particular they found boys ate more food of lower nutritional value than girls at home. Nichols et al. (2009) found that when urban middle school (grades six through eight) girls and boys did not eat lunch at school, both groups engaged in problem behaviors ranging from marijuana use (boys) to smoking cigarettes (girls). Governmental directives aimed at meeting caloric and nutritional needs of children were credited with improving calcium intake among girls (Weible 2013) and fruit and vegetable consumption among all children, particularly US minority populations in different regions (Reynolds et al. 1999). The majority of the studies in this literature grouping found positive correlations could be created between government-sponsored food policies and girls'/boys' improved lunchtime eating whether related to nutrient and caloric intake or offering lunch and keeping students in school for it. Future studies will continue to build on these findings, interrogating school food policies at national and sub-national levels.

The Qualitative Impact of Eating at School

A third force behind school food research is to understand what qualitative impact eating at school has on school performance and satisfaction with learning. The concern is whether or not eating at school (and what is eaten) improves the school experience. Ask et al. (2009) probed whether weight and academic performance might be affected by a healthier in-school lunch. They found that girls dropped weight and were more satisfied with school performance. This type of study conducted in Norway, a developed nation, and with a group of students whose SES was not identified, should not be confused with research and programming from the field of development that aimed to increase nutrient intake for the poorest of the world's school-aged children. Studies probed emotional outcomes of eating at

school in relation to academic achievement or body image (Zullig et al. 2006). Research revealed links between school lunch and the learning of a variety of social behaviors such as healthy eating habits or the consumption of fruits and vegetables. When lunch was consumed at school, drug/alcohol use decreased (Nichols et al. 2009). Zullig et al. (2006), however, found that offering free breakfast did not mean high school students ate. In this case, every group except one (African American young women) cited dissatisfaction with their bodies and practiced unhealthy eating practices including skipping breakfast. Thus eating and eating at school, specifically, was a give-and-take proposition impacted by how adolescents “digested” broader sociocultural messages about gender-body type/image. More studies are needed related to this concern; particularly absent was the impact of advertising and branding of food and food products in schools.

Constructing Research for Validity and for Gender

Research design was a fourth concern identified in extant literature. Many studies on school meal consumption were identified in preparation for writing this entry. However, the variable of gender (signifying girls and boys by N sample size) was left to the wayside as the research and/or write-up was completed. That is, the number of girls and boys was identified as a variable in the abstract and first tables or graphs only to be ignored in the discussion of findings and conclusions.

A small number of studies critiqued methodological designs (though none addressed the problematic noted above). They are important to acknowledge because of their potential impact on what is known about the relationship of school lunch and gender. The vast majority of school food studies relied on student recall, or memory of what was consumed, to measure food preferences, eating behaviors, and nutritional intake. Lyng et al. (2013) questioned the accuracy of qualitative recall measures among girls and boys. Their findings, that girls more accurately reported what was brought from home for lunch

and what was consumed, suggest a need for concern about how school food is measured in future research. These types of studies are a testament to the growth and necessity of well-crafted school lunch and gender research.

Summary

The need to take account of who is involved in school lunches, how, when, from where, with what physical and/or emotional outcomes, and why is crucial to support healthy eating practices and development in all children. Such research also encourages the equitable distribution of resources to meet the needs of student populations, supporting education for all. This entry explained school food scenarios analyzed in the literature. Also described were the differing ways that gender is applied in studies as either means of sorting girls and boys/women and men or as varied patterns that shape the school lunch dynamic. The literature addressed four concerns: rising obesity and type II diabetes among all students, critiquing the purpose of feeding at school, understanding the qualitative impact of eating at school, and, finally, how to improve school lunch and gender research.

Seed Banking, Seed Saving, and Cultivating Local Varieties

Shayna Cohen

South Kingstown, RI, USA

Synonyms

[Ex situ plant genetic resource conservation](#); [Gene banking](#); [Seed saving](#)

Introduction

A seed bank is an organization or facility used to store and preserve plant seeds, in particular varieties that are rare, have fallen out of commercial use, and/or may have unique desirable genetic characteristics.

Over the course of the twentieth century, each year, farmers worldwide grew fewer varieties of any given crop, instead choosing from a small pool of varieties that could ensure crop uniformity that contributes to efficiency and mechanization of harvest, transport, and commodity exchange. While this resulted in unprecedented agricultural yields, the focus on a few highly productive

varieties also led to decreased genetic diversity in any given farm field and thus increased vulnerability-absent genetic diversity, a single pathogen or pest can obliterate entire harvests. The United Nations Food and Agriculture Organization estimates that 75% of the world's food product diversity has been lost since 1900 (Anonymous 1999).

In response to this trend, since the 1940s, governments, coalitions of governments, and non-governmental entities have actively saved and banked seeds as a means of preserving the genetic foundation of agro-biodiversity. The world's estimated 1500 public and private seed banks – also commonly called gene banks – store an estimated six million seed accessions (not including tubers, cuttings, or seedlings which are protected in other kinds of institutions) (Brush 1999). These seed banks are widely regarded as insurance policies against global food insecurity in the face of disasters such as drought, climate change, famine, political instability, or war. Banked biodiversity is, in essence, a genetic arsenal poised to protect humanity against future unknowns. And in preserving that diversity, scientists, governments, and others preserve potential for future medical and agricultural developments.

Over generations, climates and landscapes change, and seeds adapt. As a result, seeds hold genetic resources that are suited and specific to a given place. Seed genetic diversity is also a record of farmers' experiences and decisions over the course of centuries, as they saved seeds from plants that exhibited the most desirable traits: frost resistance, high yields, pest resistance, strong nutritional profile, excellent flavor, or hardiness on marginal cropland. These locally adapted varieties are also called landraces and make up a portion of what seed banks preserve, in addition to (for e.g.) crop wild relatives, such as the wild wheat grasses from which cultivated wheat has been selected and bred.

Agricultural systems, genetic science, factors influencing food supply chains, and international politics governing natural resources preservation are irreducibly complex. The promotion and protection of crop genetic resources including local seed varieties can be sensitive, nuanced work that

engages the fields and issues of biotechnology, corporate consolidation, trade relations, agricultural policy, cultural memory, gender differentiation in agricultural systems, heritage, and intellectual property rights.

In Situ Versus Ex Situ Agro-biodiversity Preservation

The successful preservation of seed genetic diversity through seed banking is predicated on successful long-term storage under optimal, controlled conditions, including steady cold temperatures and minimal humidity. Seed banks tend to be infrastructure-heavy, with seed-drying machines, seed germination incubators, medium- and long-term cold storage facilities, test fields, and sufficient staff (primarily scientists and technicians) to store the seeds themselves as well as information about those seeds (in databases), to conduct germination tests, and to grow out the collection when necessary to resave seed in order to regenerate and grow the bank's collection. When stored in banks, seeds do not last forever, and each year fewer and fewer stored seeds will germinate (or sprout). Without dependable cold storage, regular germination tests, and regeneration efforts, a seed bank can become a tomb.

Funding is thin for agro-biodiversity preservation efforts around the globe, and thus maintenance of seed bank infrastructure is challenging for most regions and countries. It is particularly a struggle for those countries that ride an economic line, those that are categorized as “more developed” but in actuality, lack the resources to fund their own work and infrastructure (such as Greece, a country in a region of disproportionately high biodiversity, yet with limited national, European Union, or international resources to devote to agro-biodiversity).

Media attention to seed banking spiked in 2008 with the creation of the Svalbard Global Seed Vault, built into a mountainside in the permafrost on a Norwegian island between the mainland of Norway and the North Pole. The Vault is considered a “backup” seed bank, invulnerable to man-

made disasters (such as political instability that would lead to seed banks being looted for seed for cultivation and for food) or natural disasters (even in a power outage the permafrost exterior of the Vault would keep the collection frozen). Seed banks that send backups of their accessions to the Vault retain ownership of those accessions, much like a traditional financial banking institution. The Svalbard facility is unmanned and, unlike traditional seed banks, its accessions are not shared with breeders, researchers, or farmers.

As a complement and counterpoint to *ex situ* (off-site) seed banking conservation efforts are *in situ*, on-site, methods. *In situ* methods for agro-biodiversity conservation take place on farm and depend on well-trained farmers to cultivate, regenerate, and save seeds. Some see in *in situ* conservation programs the potential to improve farmers' livelihood through increased market opportunity, by empowering farmers as the stewards and curators of both seed genetic diversity and of the knowledge base it takes to cultivate those varieties. In *in situ* preservation methods, farmers stand to benefit from the process of conservation, particularly when farmers are given access to gene bank materials and are well-trained in cultivation for seed saving and in seed storage techniques and when investments are made in local agricultural infrastructure to bring agricultural yields to market (Brush 1999).

In comparison with banked seed, seed conserved *in situ* is in a constant state of change, adapting to weather, soil, and pest conditions. Farmers' priorities and preferences in seed selection also influence the pace and kind of change seen in seeds over plant generations. While most conservationists agree that both *ex situ* and *in situ* methods have a place in a broad agro-biodiversity strategy, advocates of *ex situ* conservation note that certain plant characteristics and gene expressions are lost in *in situ* approaches (through continued seed adaptation and farmer selection), while *in situ* advocates note that in *ex situ* approaches, seed genetics remain too static and unresponsive to the conditions in which they might someday be called upon to grow.

Participatory plant breeding (PPB) has emerged as a collaborative model that engages

producers as plant breeders, enabling farmers to set the goals and target outcomes of the breeding process and define the characteristics they need, granting them control over plant genetic resources, building their technical expertise, and often resulting in new products, markets, or supply chains. It is a response to the lack of agency many farmers experience in the mainstream seed marketplace, in which approximately five companies control an estimated 75% of the global vegetable seed market. PPB commonly brings together seed bankers, plant breeders, consumers, policy makers, and players across food supply chains (distributors, processors, marketing experts). This approach is most often implemented in and is most impactful in agricultural systems that are heterogeneous, smaller scale, and operating on marginal lands/soils or otherwise high-risk farming systems (Brush 1999).

Community Seed Banking, Gender, Knowledge, and Memory

In addition to national, multinational, and university research stations and breeding programs, there are numerous NGOs internationally that store and catalogue seeds; cultural organizations that celebrate and promote agricultural products and practices surrounding local varieties; and grassroots networks of farmers and their advocates who actively preserve, save, and distribute traditional seed varieties. Though these groups' motivations and strategies may vary, they share the goal of preserving agro-biodiversity for its known and unknown future potential uses. Community seed banking is a broad term that covers a range of seed saving/banking organizational typologies, including those described above. Community seed banking, seed saving, or seed library initiatives are a complement and a counterpoint to formal seed banks, the infrastructure and accessions of which are not open to or available to the public at large.

Researchers and agro-biodiversity advocates describe the concept of formal versus informal seed systems as a framework for understanding seed-saving networks, approaches, and impacts.

A “seed system,” whether formal or informal, includes all stakeholders involved in a variety of functions related to seeds, including breeding, processing, storage, packing, quality assurance, marketing, research, distribution, certification, cataloguing, growing, and regeneration. These complex systems also encompass the technology, policy, organizational structures, logistics, infrastructure, and regulations that define seeds, from development to sale to use (Mgonja 2011).

Social scientists who study seed systems (particularly those of developing nations) have noted that formal seed systems include formal organizations, agencies, entities, and infrastructures (in the sectors of education, government, business, and science). These formal systems are described as predominantly men’s domain and tend to disproportionately benefit men. Conversely, women are seen operating primarily in informal or traditional seed systems that function primarily at the community or household level: globally, in family farming operations, the labor shifts that have followed increased farm mechanization have often resulted in a shift of seed selection, saving, and management responsibilities to women. Recent research has shown that many women-operated informal seed systems (Sperling et al. 2006) in less developed countries are transforming into small-scale seed businesses that are increasingly resulting in high-quality, consistent seed.

These differences are significant for reasons of access, economics, agency, and power; they are also significant drivers of seed variety selection and, thus, which plant genetic resources are conserved. Farmer seed selection preferences as well as the kind of knowledge retained about those varieties/selections are differentiated by gender and other demographic factors (including age, socioeconomic profile, religion, and ethnicity). For example, a multi-sited study in Africa and Asia conducted by the United National Food and Agriculture Organization revealed that men tend to select for varieties that mature early, form strong seed heads, and other characteristics that better serve commercial marketplaces. Women on the other hand selected based on characteristics more relevant to family food security than

markets, including how plants performed and adapted to climate conditions, nutritional qualities, taste, and high yields (Mgonja 2011).

Since the 1980s, there has existed a movement advocating for cultural memory banking alongside seed banking, to acknowledge and record (often through oral history and interview processes) the intimate connections people and communities have with their crops and crop practices. A memory bank includes detailed information on a community’s agricultural methods, planting, harvesting, postharvest technologies, seed variety characteristics, tools, storage methods, soil types, and uses of specific crops (Nazarea 2006). This movement is particularly significant as most seed banks lack sufficient resources to adequately collect and database ethnographic information about seeds. As a result, banks often know little about the characteristics of their collection, how those seeds perform when planted, or whether multiple accessions might be genetically identical yet referred to by different names in different regions. When seed banks collaborate with farmers on in situ or participatory plant breeding initiatives, this lack of information effectively means that farmers themselves must absorb the financial risk and invest the time in learning the behaviors of seed varieties that, in comparison with modern improved plant varieties commonly sold by seed companies, are likely to require more farmer labor.

Ethics and Rights in Seed Breeding and Banking

A geopolitical reality is that crop biodiversity is not distributed evenly across the globe; rather, it is concentrated in what the early twentieth-century Russian scientist Nikolai Vavilov identified as centers of biodiversity (Nabhan 2011). In terms of plant genetic resources (PGR), regions that are rich in financial or infrastructural resources tend to be “gene poor,” and vice versa. As a result of this imbalance, there has been a long history of thought and policy related to whether and how maintainers of plant genetic resources ought to be compensated for their work and their contribution

to PGR management (Fowler and Mooney 1990; Cummings 2009).

These market-based approaches to compensation however are complicated by the fact that most of the benefits that PGR maintainers' work confers are public, whereas the seed and genetic resource industry is deeply concentrated and driven by intellectual property and patent law that favors "improvement" over preservation (Fowler and Mooney 1990). Fundamental to American property rights law (and shared by the laws of many more developed nations) is the argument that it is labor applied to resources, not the resources themselves, that creates value. Within that conceptual framework, compensation would not be due to farmers who protect and maintain raw plant genetic resources that end up as accessions to seed banks. But once breeders access that raw material and develop newly bred strains with it, the material is considered improved and thus valuable. Of course, in the case of PGR, landraces are the result of not just generations of adaptation to nature but also generations of farmer labor and selection. These legal structures limit not just compensation potential for PGR maintenance but also farmers' access to seeds and genetic materials themselves.

Several policy-related highlights from the United States and global history of the flow of rights to plant genetic resources follow.

In 1930, the United States passed the Plant Patent Act, which for the first time gave plant breeders patent control over newly bred varieties of plants that asexually reproduce. In 1970, the Plant Variety Protection Act passed in the United States. This intellectual property statute granted plant breeders 25 years of control over plant varieties that sexually reproduce, based on the breeders' ability to prove ability to prove that the variety was novel, uniform, and stable. Perhaps the most significant exemption written into this Act granted farmers the right to save their own seed from these bred varieties and even to sell seeds to each other. As a result of these exemptions, in the United States, there were high rates of farmer seed saving, even among farmers of commodity crops, through the early 1980s (Kloppenborg 2005).

Around the same time, in 1971, on an international scale as part of the Green Revolution, the Consultative Group on International Agricultural Research (CGIAR) was created with support from the Rockefeller and Ford Foundations. Headquartered in Rome but operating autonomously, the CGIAR built 15 research centers around the world, centralized in Vavilov's centers of biodiversity and, thus, concentrated in the global geopolitical south. CGIAR was and is devoted to increasing global food security through management of natural resources, especially plant genetic resources. While advances at CGIAR research stations have been much celebrated (including breeding programs that improved yields and in some cases nutritional profiles of a range of crops), the organization has also been criticized for institutionalizing the flow of plant genetic resources, power over those resources, and access to the value of those resources from less to more developed countries (Kloppenborg 2005).

In 1983, under pressure from the developing world, the United Nations FAO drafted an International Undertaking on Plant Genetic Resources for Food and Agriculture that included a clause that identified plant genetic resources as the "common heritage of mankind." In practice, this clause was a strike against efforts for compensation to producers and maintainers, as plant genetic resources found within one nation's borders or one community's property lines could not necessarily be considered privately owned (Fowler and Mooney 1990).

Meanwhile in the United States, in 1985, the first utility patent (a patent structure that exists outside of the Plant Patent Act) was granted on a plant: corn. This was significant because utility patents cover not just the plant variety itself but all the component parts of that variety and because, unlike the Plant Patent Act, utility patents do not include exemptions for farmer seed saving. The farmer seed saving exemption was then removed from the Plant Variety Protection Act in 1994, severely limiting US farmers' right to select and save seed and paving the way for the patent-based and litigation-heavy system that has defined the implementation of biotechnology and

plant genetic modification (as opposed to traditional seed breeding methodology which has been the subject of this article) (Kloppenburg 2005).

In 1989, a UN FAO resolution made landrace maintenance worthy of compensation, and an international fund was created to fund that compensation. However, contributions to that fund were voluntary and never significant. In 1992, the International Convention on Biodiversity was drafted without inclusion of provisions for farmers' rights (seed saving rights, specifically), a move that some historians have noted effectively ended the international discussion on "common heritage" and compensation. The UN FAO's International Treaty on Plant Genetic Resources for Food and Agriculture, entered into law in 2004, sought to harmonize and update the 1983 International Undertaking for Plant Genetic Resources for Food and Agriculture with the Convention on Biodiversity. The treaty includes stronger language on farmers' rights than the undertaking that preceded it, as well as a mandate on profit sharing for cultivar developed from genetic materials borrowed from gene or seed banks. However, it does not cover all key food and forage crops (Cummings 2009).

Marketing Landrace Seeds and the Foods They Yield

Internationally, the seed trade is a very tightly controlled and standardized industry in order to guarantee farmers and seed buyers a uniform, consistent, reliable, and predictable product. Since the 1970s, the European Union, for example, has overseen the marketing and dissemination of seeds in its member countries through its Common Catalogue. Each member country produces a national catalogue of seeds that has passed rigorous uniformity standards, and these national catalogues are then compiled into the Common Catalogue. Seed that does not pass these rigorous standards and does not appear in the Common Catalogue cannot be sold. Though landrace seeds possess characteristics that plant scientists, farmers, and consumers celebrate (such as

drought resistance, ability to perform well in marginal soils, or unique tastes, shapes, or colors), few perform in a uniform or predictable way. Thus trade of landrace seed itself – and opportunities to employ market-based solutions to increase trade of landrace seed – is limited and at times illegal (Cohen 2011).

Absent international political or financial structures to compensate maintainers of plant genetic resources or to develop strong markets for landrace seed, several market-based solutions have arisen to promote the foods these seeds yield, the most notable of which is geographic indication (GI) standards and labeling. Country by country, there are different legal structures under which GI is practiced. Ultimately, a geographic indication scheme is a legally defined set of standards for food and beverage products, the goal of which is to enable producers (farmers and producers of value-added products) to differentiate their products in the marketplace based on place, origin, heritage, production processes, and tradition, rather than making them compete on traditional market criteria of volume, marketing, or pricing. For consumers, the purpose of a GI label is to guarantee a link between a product's origin; that place of origin's natural resources, culture, processes, and practices; and overall product quality.

While landrace conservation, plant genetic resource maintenance, and agro-biodiversity are not explicit objectives of GI, some economic research has drawn links between genetic resource conservation and the creation of strong GI-based value chains. GI schemes have been found to support agro-biodiversity by making crop varieties and the unique food products they contribute to be economically viable, and when those varieties are economically viable, farmer's plant and preserve them. There have also been documented instances where GIs have resulted in negative impacts for plant genetic resources, for example, by highlighting products that specialize in certain landraces to the exclusion of others (Larson 2007). Still, successfully marketed GIs can result in recovery and reinvigoration of endangered plant genetic resources themselves and markets for products utilizing those resources, in particular, when genetic and crop management is a close

cross-sector collaboration between the producer, a gene bank, food supply chain stakeholders, and regional agricultural research institutions.

Summary

The world's estimated 1500 seed banks hold millions of accessions representing the plant genetic resources that form the foundation of plant breeding and cultivar development for agriculture's future. In light of the dearth of international resources devoted to maintaining seed bank infrastructure and shifting climate patterns that impact agricultural performance and seed variety choice, formal seed banking alone is essential but insufficient. In combination with participatory plant breeding, in situ preservation methods, informal seed saving and distribution networks (and international policy that supports farmers' right to engage in seed saving and trade), memory banking of agricultural ethnographic and plant physiology data, and strong value chain development for the foods these banked varieties can yield, seed banks are the crucial foundation of an integrated plant genetic resources preservation strategy.

[Shifting cultivation](#); [Swidden cultivation](#)

Introduction

Slash-and-burn agriculture (Peters and Neuenschwander 1988; Palm et al. 2005), also called swidden (Mertz et al. 2009) or shifting agriculture or cultivation (Nye and Greenland 1960; Robison and McKean 1992; Aweto 2013), typically refers to land uses where a cropping period is rotated with a fallow period that is long enough to enable the growing of dense, woody vegetation and where the biomass is eliminated from the plot by cutting, slashing, and burning it, prior to the next cultivation cycle. It is generally considered an

extensive land use, maintained through time by expansion over uncultivated land following population growth (extensification), in contrast with more intensive land uses, where the biomass is incorporated to the soil through plowing or other practices. It encompasses a great variety of systems (Schlippe 1956; Conklin 1957; Miracle 1968; Rappaport 1984; Dove 1985; Fresco 1986; Ramakrishnan 1992; Schmidt-Vogt 1999; Denevan 2001; Shaoting and Fiskesjo 2001; Whitmore and Turner 2001; Palm et al. 2005; Pollini 2007; Cairns 2007; Saxena et al. 2007; Mertz et al. 2009; Tr  n et al. 2009; Cairns 2014) that differ by the ecosystems being cleared, the landscapes being produced, the duration of cultivation and fallow periods, the management of fallow land, the crops being cultivated, and the techniques being used.

The terms slash-and-burn, swidden, and shifting cultivation are often used interchangeably, although they outline different aspects of the system. Slash-and-burn refers to the way the biomass is eliminated after clearing: by setting it afire, in contrast with slash-and-mulch systems (Thurston 1997), usually practiced in areas with no dry season, where the biomass is left to decompose. The term “swidden” refers to the act of burning a biomass in order to cultivate it. It is the closest synonym to slash-and-burn and is often preferred to this term, because it does not outline the acts of “slashing” and “burning,” which would be conducive to negative prejudices. But it is rarely used in cases of slash-and-burn systems with short fallow. Shifting cultivation evokes the idea that fields are shifted from one location to another and that the land is not permanently cultivated. It encompasses both slash-and-burn and slash-and-mulch systems but, like for swidden cultivation, is rarely employed in case of systems with short fallow, where cultivation is close to permanent. It is also misleading as it suggests that the land is abandoned and idle after a few years of cultivation, which is generally not the case. In this entry, the term slash-and-burn agriculture is adopted in order to encompass systems with long or short, herbaceous or woody fallow, where the biomass is actually being slashed and burnt.

Characterization

Slash-and-burn agriculture is a widely adopted and sometimes inescapable strategy to practice agriculture in forested landscapes. Most staple annual crops require full exposure to the sun in order to grow; hence areas of forest need to be cleared to establish new fields. This offers great sanitary conditions to crops because their main competitors (weeds) and threats (pests and diseases) are destroyed, except for wild animals if some forest remains around the field. Burning the biomass further provides nutrients that deposit on the soil in the form of ashes. After one to a few years of cultivation, weeds, pests, and diseases start to appear and nutrients are washed away or have been utilized by the crop. The field is then temporarily left to fallow, but will be cleared and cultivated again once a secondary forest or sufficient biomass will have regrown.

The fallow period usually lasts 3–25 years, depending on climate and edaphic conditions and the techniques being used. Its purpose is to reconstitute a stock of biomass that can be mobilized again through burning and to eliminate weeds, pests, and diseases. A longer period is technically unnecessary and would result in additional burdens for cutting larger trees. A shorter period is usually conducive to disappearance of woody vegetation, which triggers a fertility crisis or significant technical changes. When the vegetation is dominated by grasses, the use of fire is abandoned or a slow burning is practiced in order to reduce nutrient and carbon losses. Vegetation is peeled off the land together with its root mat, stacked into heaps, sometimes covered with soil, and charred. This technique, called “paring and burning,” differs from slash-and-burn and is not considered in this entry.

Crops cultivated in slash-and-burn agriculture systems vary greatly. Several crops are associated, which gives to the field a messy appearance, with stumps, incompletely burnt logs, and spared canopy trees littering the field. But there is order in this heterogeneous environment. Farmers adapt to the heterogeneity of their fields by varying crop associations and spacing. They can plant

shade-tolerant species (bananas, plantain, taro) under remaining trees, pumpkins and other vegetable on the most fertile spots, and cereals (corn, sorghum) and legumes in open areas.

Perennial woody crops can also be planted, in which case they continue to grow during the fallow period. Useful natural trees are also favored, by being spared during the clearing and weeding, given some care during the fallow period, and sometimes actively planted. There is thus no straight line separating slash-and-burn agriculture from more intensive cultivation systems. Perennial crops like cocoa or coffee can be associated with annual crops after clearing. They succeed to these crops in the same way as would the fallow vegetation otherwise, until the aging plantation, which often takes the form of a forest with a closed canopy, is rejuvenated by starting a new cycle or remains as a permanent agricultural system called agroforest.

In spite of its suitability to forest environments, slash-and-burn agriculture is rarely practiced alone. Most farmers combine it with other land uses like home gardens, irrigated fields, or permanent fields of perennial crops. Slash-and-burn farmers also typically practice hunting, gathering, and fishing, activities whose importance is proportional to remaining forest cover.

Economic Rationality

Slash-and-burn agriculture is practiced all over the world in forest land with wet climates and low population density. This is not a coincidence. It is often the most rational land use in these conditions, and it can be maintained in spite of population growth as long as forest land remains, through extensification.

When population density is low, land is abundant while labor is usually a strong limiting factor to put more land into production. Like other economic agents, slash-and-burn agriculture farmers search for the maximization of output for a given level of input of the scarce resource, labor in their case. Slash-and-burn agriculture enables maximizing labor productivity for three main reasons:

- First, slash-and-burn agriculture with long fallow does not require much work once the crops have been sown. Clearing the forest requires heavy work but is done by men, who do not have to carry significant domestic tasks, and is not constrained by tight deadline as it is done off season, during the dry period. Once the biomass has been burnt, crops are typically sown by men and women, the latter being often in charge of most maintenance operations until harvest, at least in African countries. Slash-and-burn agriculture with long fallows limits weed invasion because weeds typically grow less abundantly in primary or old secondary forests. This is probably the main advantage of the system and the main cause of its high labor productivity. This advantage is progressively lost with the reduction of the fallow period. The reason for abandoning the field after a few years of cultivation is often weed invasion, rather than or as well as decreasing soil chemical fertility. Weeds may thus be the key constraint to adopting permanent cultivation, because of the labor required for weeding.
- Second, slash-and-burn agriculture does not imply plowing the land, an operation that requires a lot of work if done manually. Crop roots do not need to penetrate deep into the soil as nutrients are concentrated close to the surface after the burning. Plowing would anyway be impossible or excessively burdensome because of the dense root mat and the many stumps that cover the soil.
- Third, even though yield (output per acre) maximization is not the purpose, slash-and-burn systems usually have quite high yield at least when practiced with long fallow. Fertility depends on the amount of biomass that can be burnt, as much as on the soil's chemical properties. Even soils reputed to be infertile like ferralsols can yield high if a long fallow can be practiced.

The Limits of the System

Slash-and-burn agriculture is generally regarded as a sustainable land use when long fallow can be

practiced, that is, when the initial fertility can be reconstituted after the cultivation cycle. This is generally possible with a population density below 35 inhabitants per square kilometer (Mazoyer and Roudart 2006), although it greatly depends on ecological conditions. When population density increases, which can be caused by high birth rate and/or migration, the fallow period typically decreases. Fewer nutrients accumulate in the biomass and are returned to the soil in the form of ash. With a very short fallow (1–3 years), the vegetation is dominated by herbaceous plants whose roots do not penetrate deep into the soil. This root mat can slow down leaching by capturing nutrients, but it does not bring additional nutrients to the soil, as do trees whose roots access the bedrock where mineralization occurs. A shorter fallow period also favors weed invasion, pests, and diseases. The addition of these effects can trigger a fertility and/or a labor crisis. Yield per acre decreases, while labor requirement to cultivate the same surface increases. Beyond a certain threshold, the system cannot be sustained. It does not produce enough food to provide the caloric intake required for the work of the next growing season, unless technical changes occur. The system must evolve. New techniques and strategies are thus required, and created or adopted, to escape the dead end.

The Evolution of Slash-and-Burn Agriculture Systems

Slash-and-burn agriculture is probably one of the oldest agricultural land uses. It has been practiced worldwide, from the tropics to temperate regions, and is still practiced widely in the tropics. But in many regions, it has been abandoned, sometimes for centuries or millennia, and alternative land uses developed (Boserup 1965; Angelsen and Kaimowitz 2001; Brookfield 2001; Mazoyer and Roudart 2006; Cairns 2007). Looking at history and ongoing changes enables us to anticipate future land-use changes in areas where slash-and-burn agriculture is still practiced.

Two main strategies are adopted by farmers when they face the limits of slash-and-burn

systems. They combine slash-and-burn agriculture with other land uses and activities, and they progressively transform the slash-and-burn system itself. They usually combine these two strategies, which we will detail separately here.

The Combination of Slash-and-Burn Agriculture with Other Land Uses and Activities

Slash-and-burn systems provide staple plus a broad range of other products. But they are often practiced alongside other land uses and activities, even in the absence of crisis. Fruit trees are frequently planted in proximity to dwellings, while permanent gardens of vegetable and sometimes staple crops are established on the most fertile soils. Slash-and-burn farmers typically practice hunting, fishing, and gathering and raise animals. Livestock substitutes to wild animals when hunting success is low, that is, when higher population density increases. Women (or, in some groups, men) make and sell various crafts like baskets or woven mats, an activity that requires a lot of work but not a lot of energy as it is done at home. The search for seasonal jobs and temporary or permanent outmigration are also common practices. When the fallow period reduces and slash-and-burn agricultural fields do not produce enough, all these activities, except hunting, fishing, and gathering who decrease when forest resources decline, can become the most important sources of food and income.

A frequent pattern is that when the crisis occurs, farmers move down to cultivate bottom land. Slash-and-burn agriculture is mostly practiced on hillsides because this type of land drains better, which is an asset in wet climates. Bottom land, to the contrary, is often avoided because of flooding risk and heavy wet soils. But when erosion occurs, nutrients are lost on slopes and accumulate on bottom land, which becomes increasingly attractive. To cultivate bottom land typically requires heavy labor investment, though, in order to drain the excess water or to irrigate the land, in order to escape dependence on rain and avoid flooding risk. But cultivation can then be

done during the dry season, which spreads the labor burden more evenly over the year.

A second frequent pattern, which often combines with the first, is the establishment of perennial crops on eroded slopes not suitable anymore for slash-and-burn agriculture. Perennial crops are often cash crops like cocoa, coffee, palm oil trees, rubber trees, cloves, and cinnamon. This strategy is often associated with the development of infrastructure and better connection to markets.

The Progressive Transformation of Slash-and-Burn Agriculture Systems

Alongside this diversification, reduced fallow periods can trigger, or contribute to trigger, a deep transformation of the slash-and-burn systems themselves. Under a certain threshold, the fallow is too short to enable the development of woody perennials. The stumps of large trees rot progressively, and the root mat becomes less dense. Hence it becomes possible to practice paring and burning and/or to plow the land. When this situation occurs, plowing tools are usually already known, because plowing is practiced in neighbor villages with higher population density, or in one of the systems that farmers practiced already alongside slash-and-burn agriculture.

Plowing enables extirpating the roots of the most invasive remaining perennials. This cleaning of the underground through plowing constitutes, after clearing, a “second step” in the long-term process of preparing land for permanent, intensive cultivation. The field is then cleansed from both aerial biomass, which is eliminated through slashing and burning, and soil woody biomass, eliminated through short fallow and plowing. After the colonization of the forest frontier, a “second frontier,” the soil, has been opened and is ready to be exploited at greater depth, which compensates for the lower nutrient level produced by burning a short fallow. Typically, farmers then adopt a more complex and longer crop rotation. They often plant cereals, followed by or associated with legumes, followed by tubers, before leaving the plot into a short fallow dominated by grasses and other herbaceous plants. In certain condition,

however (fragile soils, steep slopes, heavy rain), plowing requires improvements like terracing in order to be practiced.

As intensification proceeds, new strategies to maintain soil fertility need to be adopted. In slash-and-burn systems, nutrients are brought to the plot by fallow vegetation, which pumps them deep into the soil. They are made available to the crops in the form of ash, through burning. With short herbaceous fallow or no fallow, this nutrient supply is lost. At first, a more efficient nutrient management (crop rotation, plowing, paring and burning, zero burning) can suffice to maintain decent yield. But in the long term, a new source of nutrients needs to be provided. Typically, farmers develop animal husbandry, taking advantages of the new grazing resources of short fallow dominated by grasses, and start to use animal manure. At first, they observe that crops yield more when cultivated in a corral so they rotate corrals and fields. But with increasing pressure on land and nutrient need, they start to actively manage manure by collecting it in corrals and transporting it to fields. If animals graze in fields, this represents an improved nutrient management but not a significant net gain since nutrients are taken from grass growing on the same land as the crops. If they graze in uncultivated pastures, this represents a net gain through horizontal transfer of nutrients by animals from pastures to agricultural land, in the form of manure, which replaces the vertical transfer by fallow trees, in the form of ash Mazoyer and Roudart (2006).

Constraints to the Evolution of the System

The evolution of farming systems outlined above has been observed, with very similar patterns, in many regions of the world. It is encouraged by necessity when population density increases. But it does not automatically occur as it also faces strong constraints.

One key constraint is the low investment capacity of slash-and-burn farmers. The practice of slash-and-burn agriculture relies on bestowed natural capital. It simply requires an ax and a

machete and generates a high output for a relatively low labor input, at least when long fallow can be practiced and when hunting and gathering contribute to food security. Other land uses require more efforts, to plow the land, eliminate the weeds, and proceed to land improvements. As long as they are practiced with a hoe and other manual tools, they typically require more work for the same output. More efficient tools need to be adopted (such as a plow, a cart, and a pair of oxen to produce manure and pull these tools), or significantly higher yields need to be obtained (through the use of chemical fertilizers, pesticides, and herbicides) to render the new systems more labor efficient. The acquisition of such equipment or inputs, that is, the substitution of a human-made productive capital for the natural capital, is probably the main constraint to phasing out slash-and-burn agriculture. It is rendered difficult by the fact that slash-and-burn agriculture is often practiced in remote areas with limited connection to market and few income generation opportunities to farmers, although this is not a rule. There are many cases where slash-and-burn agriculture has been abandoned without adopting animal draft or chemical inputs, but farmer communities in this situation are usually very poor and food insecure.

The development of perennial crops, however, is an exception to this general pattern. When perennial cash crops are available and can be sold a good price, they can sustain a family with limited labor input and using a relatively small surface. As long as land is not an overly scarce resource, perennial crops can be associated with indigenous species that provide a broad range of goods and services and render the system more resilient to ecological stresses and economic shocks. Such systems, called agroforests, are developed progressively out of slash-and-burn systems and do not need significant investments. But when land becomes scarce, they tend to be abandoned in favor of more intensively managed plantations that face the investment constraints described above.

A second important constraint is the risk factor. The development of new systems creates new risks and requires the production and mastering of new knowledge in order to reduce these risks.

This explains the preference of farmers to diversification rather than specialization, and for a progressive transition during which both slash-and-burn agriculture and the new system are practiced, rather than large investments and elimination of their traditional land uses.

A third important constraint is the discount rate. When slash-and-burn systems are in a situation of crisis, food security is usually hardly achieved. In this context, investing labor for late reward is not an easy option, which often explains the reluctance to adopt conservation farming techniques.

Environmental Impact

The environmental impact of slash-and-burn agriculture is a very controversial issue, biased by political positions on both sides of the debate. Slash-and-burn agriculture requires clearing primary forest and leaving a secondary forest growing before clearing it for repeating the cycle. This clearing of forests is often criminalized by states and receive strong opposition and critique from organizations committed to biodiversity conservation, while the mosaic of primary and secondary forests that is typical of slash-and-burn agriculture landscapes is praised by social scientists and activists having sympathy for community or “traditional” ways of life.

If one escapes this political ground, the reality is in fact quite simple. Slash-and-burn farmers clear primary forests, just like any other farmers willing to grow staple crops that demand sunlight. They clear more areas to obtain a given output than farmers practicing more intensive systems, but they do not clear the land permanently. For a given population with a given level of needs, slash-and-burn agriculture landscapes may have less primary forests and more secondary forests than more intensively cultivated ones. The environmental impact of each system, for a given output (*ceteris paribus*), thus depends on the value given to primary versus secondary forests. If biodiversity is to be conserved, it would be more rationale to cultivate less land, permanently, by adopting more intensive systems: the so-called

“land-sparing” model. Primary forests are indeed mosaics of primary and secondary vegetation. They are pieces of land at various stages of vegetation development, because secondary succession occurs after the death and fall of large trees, so both early and late successional species would be conserved. Young secondary forests like those found in slash-and-burn agriculture landscapes, on the other hand, lack large stands of late successional species, because the complete secondary succession typically lasts a century or more in tropical forests.

The reality is quite simple, but not that simple, however, which puts into question the land-sparing model. The *ceteris paribus* clause makes sense if the purpose is to outline specific processes in a closed system, which is only the first step of understanding realities, which are open systems. Variables cannot be isolated from each other in the real world, meaning that at some point, the *ceteris paribus* clause needs to be abandoned if science is to inform policy makers (Pollini 2007).

In other words, the evolution from slash-and-burn agriculture to alternative systems is not simply a change from using more land to using less land for the same output. Other changes can occur, like an increase in farmers’ needs and total output. Once investments are done and the labor productivity bottleneck mentioned above disappears, output per household can be doubled or more, and benefits can be reinvested in the expansion of cultivated land. The formerly slash-and-burn agriculture landscape then becomes suddenly attractive. Outmigration decreases, while immigration increases, sometimes with the support of government incentives, and the forest frontier is pushed forward. The poorest farmers, who do not have sufficient resources to follow this path, are often outcompeted by the most economically favored segments of the population. Poor farmers become socially marginalized and move to the first line of the frontier where they continue practicing slash-and-burn agriculture with long fallows, which perpetuates the blame put on this land use, whereas the whole process was triggered by the combined effects of increasing cultivated area per farm and attracting more farmers, two frequent corollaries of intensification. In the

worst case, the development of infrastructure attracts large-scale international investors who establish plantations to satisfy a virtually infinite global demand, like palm oil plantations established for biofuel production.

In sum, the transition from slash-and-burn agriculture to alternative land uses is part of an historical process that has multiple facets and is to be considered holistically if social and environmental improvements are to be achieved. Within this broader framework, slash-and-burn agriculture can be a cause of as well as a buffer against deforestation. Moreover, beyond the issue of deforestation, it must also be pointed out that slash-and-burn cultivation in self-sufficient societies does not require a single drop of fossil fuel to be sustained, contrary to most of its so-called alternatives.

Policies

In most regions of the world where slash-and-burn agriculture is practiced, it is targeted by policy makers who aim to eliminate this practice, because of blames and prejudices regarding its environmental impact (Fairhead and Leach 1998), because of willingness to allocate forest land to other land uses and stakeholders, and because of ignorance about the context within which farmers cut trees. The domains of ignorance that characterize policy making are briefly reviewed here.

First, the proposed alternative land uses are usually designed based on the assumption that yield per acre matters, because obtaining high yield is the goal of most agronomists and extension agents working in agricultural projects. This is what they have been trained to do. The labor and investment bottlenecks and the risk and discount rate factors evoked above are usually overlooked, which leads to non-adoption of the proposed techniques, except for local elites, quite often foreigners or recent migrants, who already have some investment capacity. "Support" to slash-and-burn farmers then can favor a social differentiation or resource capture that contributes to the marginalization of slash-and-burn agriculture farmers and the persistence of their

dependence on tapping natural resources, while the "successful" farmers who adopt intensive techniques invest their income in land acquisition and encourage further forest clearing.

A second frequent mistake, or at least a counterproductive approach, is that the techniques being proposed are framed within a sustainability paradigm that assumes that resource stocks should be kept constant. It is argued, for instance, that forest biomass and the nutrient content of soils should not be reduced. This is at odd with the logic adopted by most economic agents, including smallholder farmers, who are committed to substituting resources once they are depleted, rather than maintaining their stock constant. If the shift to a new resource (B) can be achieved before the previous resource (A) is completely depleted, then the crisis can be avoided. Once resource B is adopted, resource A is relieved from pressure and can recover. This is what happens, for instance, in cases of forest transitions. If they adopted a more flexible conception of sustainability, conservation and sustainable development organizations could provide support that help farmers to shift to resource B before resource A is completely depleted. Moreover, if it was accepted that the stock of resource A does not need to stay constant, then tapping into this stock could generate the means to build resource B. Nobody knows how long a given resource can last, and certainly no resource can last forever, but within policy time frames, this point should be taken into consideration.

To illustrate this with a practical example, resource A can be land on hillsides where slash-and-burn agriculture is typically practiced. Resource B can be bottom land. Farmers often shift from hillsides to bottom land when slash-and-burn agriculture is in a situation of crisis because of short fallows. The depletion of resource A (nutrient losses through erosion) contributes to the building of resource B through the accumulation of nutrients in bottom land. If projects attempt by all means to maintain farming activities on hillsides, by designing new systems like contour lines, improved fallow, or other technologies that farmers do not adopt because of labor, investment, risk, and/or discount rate

issues, then innovation and investment opportunities can be lost, and the transition to bottom land cultivation can be hampered. If support is allocated to improving bottom land instead, by realizing investments that farmers were already envisioning (terracing, irrigation schemes, supply of equipment like animal draft, development of livestock husbandry), then the transition can accelerate. With higher support to bottom land cultivation, the shift to new land uses will be faster, and more resources will remain on slopes in the end. Land will not be degraded to the point that vegetation cannot recover, and forest fragments will remain from where the original ecosystem will be able to recolonize space. In a false paradox, hillside vegetation would recover better if nobody cared about it and supported denaturalizing further the bottom land instead.

Third, fallow land in slash-and-burn system is often considered idle land by policy makers, as reflected in the misleading term shifting cultivation. Fields do not exactly shift in “shifting” (slash-and-burn) agricultural systems. They are permanently established but alternate periods of cropping with periods of fallowing, with fuzzy boundaries between the two. Fallow land is often actively managed, through enrichment with useful trees and care of remaining cultivated perennials. It is typically managed by the same individual families who grow the crops, unless it remains uncultivated beyond the typical fallow period, in which case the plot can be reintroduced into community land. Overlooking this fact, policy makers are tempted to deny the right of slash-and-burn farmers over fallow land, which is conducive to misguided policies that further marginalize them.

How, then, should slash-and-burn agriculture be addressed by policy makers? First, it should not be criminalized or blamed and should not even be considered as a land use which, comparatively with others, deforests more land. There is quite a broad agreement that large-scale deforestation is mostly triggered by commodity booms and large-scale agribusiness investments on forest frontiers, from the development of cattle ranching and soybean cultivation in the Amazon to palm oil production in Southeast Asia. In this context, securing the rights of local farmers practicing

slash-and-burn agriculture could be a buffer against large-scale deforestation, like is securing the rights of hunting and gathering groups. Second, the transition to more intensive land uses could be favored by increasing the range of land-use options available to smallholder farmers, from access to new tools and inputs to the so-called ecological intensification. The latter has the great advantage of relying on human labor and natural capital rather than financial investments and further artificialization of the environment. But it remains doubtful whether it could maintain a satisfactory level of labor productivity, and hence a satisfactory livelihood, unless high-value products can be sold and/or fair trade markets can be captured. Smallholder farmers can be more easily seduced by productivity leaps permitted by animal draft and the use of chemical inputs than by ecological intensification. They are willing to buy more goods, send their children to good schools, access healthcare, reach middle-class livelihood, and enter into “modernity” like other citizens. There is a risk that an excessive emphasis on ecological intensification leads to denying them the right to engage more conventional, straightforward pathway to “development,” and one has to be cautious about this pitfall.

Summary

Slash-and-burn agriculture is a land use that represents an early step in agricultural history. It is practiced in locations where forest resources are still abundant. It typically implies the conversion of primary forests into a mosaic of secondary forests at various stages of development, but not the definitive elimination of forest. Primary forest clearing occurs progressively, though, as a way to maintain the same fallow period in spite of population growth. When no primary forest remains (or when the remaining primary forests are all protected, by local customs or conservation policies), the fallow period reduces, secondary forests eventually disappear too, and new techniques emerge or are adopted. The natural capital is progressively replaced by man-made productive capital, or the system enters into a crisis, depending

on whether the constraints to these changes can be levered. In theory, the new land uses that emerge enable preserving more forest, because they require the use of less land for producing the same output. In practice, they trigger or are accompanied by a series of more radical changes like the development of infrastructure, migrations, financial investments, and new consumption patterns, which typically provoke larger-scale deforestation.

In spite of this, slash-and-burn agriculture continues to be blamed for being the main cause of deforestation. Shortsighted policy makers fail to contextualize the act of cutting trees and are biased by modernization myths that see slash-and-burn agriculture as a primitive land use. Slash-and-burn agriculture is a primeval land use in the sense that it preceded others in many regions of the world. But no value judgment should be attached to this statement. At a time of increasing doubts about mainstream development pathways, slash-and-burn agriculture should be seen as an opportunity not to fall into productivist, unsustainable models. But this is not to say that slash-and-burn farmers should remain trapped with this “primeval” land use. They have the right to evolve and change, as did other societies before. In our globalized society, they should be given access to the same range of economic and technical options that are made available to other farmers.

In between the quest for sustainability and attempts to escape from poverty, smallholder farmers practicing slash-and-burn agriculture must be paid a great attention as they will continue to be key targets of conservation and development programs. If proper decisions are to be taken, that is, if they are to be given the possibility to control their future and increase their production while generating public goods, they will have to be listened to, away from prejudiced views that criminalize or idealize their choices, depending on which political agenda frames the debate.

Slow Food

Joseph Campisi
Department of Philosophy, Marist College,
Poughkeepsie, NY, USA

Introduction

Slow food is a recent food movement. Unlike other food movements, however, such as the campaigns to “eat organic” or “eat local,” slow food is closely associated with and influenced by the programs and policies of an international organization which is itself called “Slow Food” founded in Europe in 1989 (Irving 2008; Malatesta et al. 2005). One need not, however, be an official member of Slow Food to follow the movement’s ethos. Slow food is primarily a rejection of fast food and fast-food culture, and its followers claim that food that is “slow,” that is, food that is carefully prepared using minimally processed ingredients according to time-honored cultural traditions, is superior in taste and quality to the highly processed, generic, and standardized fare that typifies much of the fast and processed food industries. Adherents of slow food also maintain

that food is more properly enjoyed when it is consumed at a leisurely rate in the company of others, as opposed to the frenetic and solitary eating that is motivated by fast-food culture.

Since its inception, slow food has inspired similar movements beyond the purview of food, and its core principles have been applied to things such as local economies and urban planning (Parkins and Craig 2006). So, for example, proponents of Slow Cities (*Cittaslow*) encourage the implementation of measures that would promote “slow living,” restrictions on vehicular traffic, improved park systems, etc.

As for slow food, its followers are particularly concerned with the quality of food, slow vs. fast, but they also express interest in other issues related to food, in particular, environmental factors related to food production and worker rights. This wider array of concern is especially evident in the organization Slow Food which in its platform promotes food that it describes as “good, clean, and fair” (Malatesta et al. 2005; Petrini 2005). While the movement itself offers no explicit philosophical or ethical foundation for its various practices, parallels can be drawn between its position regarding food and food consumption and the ethical theories defended by figures such as David Hume, Epicurus, and Aristotle. The movement, however, has also been subject to a variety of criticisms and has been accused, among other things, of being elitist and anti-environmentalist.

Philosophy and Ethics. Identifying a complete and coherent set of ethical principles underlying slow food is difficult insofar as there are informal followers of the movement and an official organization, all of whom do not necessarily defend or place an emphasis on the same set of values. Insofar as the organization plays an influential role in guiding the philosophy and practices of slow food, attention will be focused in what follows on the ethical motifs underlying Slow Food.

According to its mission, Slow Food defends three central values in relation to food, maintaining that it should be “good,” “clean,” and “fair.” “Good” refers to food’s quality, its flavor and taste. “Clean” food is food that is produced using sustainable farming and production

practices that do not cause unnecessary harm to the environment. “Fair” food is food that reflects a commitment to social justice and to fair compensation for farmers and food producers.

Good food. Slow Food’s concern with what they understand as “good” food has been dominant in the movement from its very beginning. As its name implies, Slow Food perceives itself as a response to “fast food” and “fast-food” culture. For the founders of Slow Food, the problem with “fast food” and the “fast life” within which it is consumed is not necessarily the speed with which food is produced per se (i.e., there can be “good” fast food in their sense) but its standardization and homogenization, features of food that, they believe, mark much of contemporary food culture and industry. Food in a “fast-food” society is, they argue, transformed from something to be enjoyed and savored in the company of others to something that merely serves to sustain us physically while eaten quickly on the go. Moreover, the rise of industrial and global agriculture they maintain has been accompanied by a concomitant fall in the diversity of food as food varieties and local food traditions vanish in the face of things such as monoculture and corporatization.

For defenders of slow food, fast food thus prevents people from experiencing true pleasure in their food. They view fast food as basically bland and tasteless, highly processed and standardized fare, produced with quantity in mind over quality, lacking any real connection to a particular culture or place, designed to be eaten quickly and mindlessly. Recovering true gastronomic pleasure, they believe, can be achieved by pursuing food that is, in Slow Food’s terms, “good.”

“Good” food, according to Slow Food, is food that is produced with quality in mind, food that is delicious, distinctive, and flavorful. Proponents of Slow Food recognize that taste in food is subjective and that different individuals will ultimately find enjoyment in different foods and flavors, but they contend that, in general, certain food and food products can be identified as “good” (Petrini 2005). These would be foods that produce pleasant taste sensations and are, generally, as “natural” as possible, respecting the product’s original characteristics. Such criteria, they contend,

rule out much “fast” or industrialized food insofar as it is often flavorless and highly processed.

Slow Food’s contention that judgments about “good” food can be made despite the subjective nature of taste recalls the position on aesthetic judgment defended by David Hume (1963). For his part, Hume also acknowledges that, when it comes to matters of taste, there exists a variety of opinion as to what different individuals and different cultures deem to be beautiful or good. This leads him to recognize the distinction between objective matters of fact and subjective feelings or sentiments about objects, where beauty, it would seem, is entirely in “the eye of the beholder.” Nevertheless, Hume maintains that general standards in regard to aesthetic taste can be defended, that we can justifiably deem some things to be superior to others, and that we make these kinds of aesthetic judgments all the time.

This ability to pass aesthetic judgment, Hume argues, is made possible insofar as all humans as humans share a “universal structure” that typically leads them to be pleased by certain experiences and displeased by others. This does not mean that everyone will always appreciate the same things. The proper appreciation of an art object, according to Hume, requires certain conditions, e.g., serenity and attentiveness, but it also requires, in his estimation, the possession of “delicacy” or “sensitivity,” the ability to discern or recognize the aesthetic traits or features in a given object. Such aesthetic sensitivity, Hume argues, can be developed in individuals by training and practice. Repeated exposure to a variety of artworks, he contends, can help individuals gain the sensitivity required for a discerning taste.

Following Hume, some sense can be made then of Slow Food’s defense of “good” food. While acknowledging the fact that not everyone is going to be drawn to certain tastes and flavors, followers of Slow Food maintain that we can nevertheless judge certain foods to be “good” or superior to others, e.g., artisanal cheeses over processed cheese food. Recognizing such superiority, however, requires a certain amount of discernment, and the focus on taste education in Slow Food, the “Taste Workshops” it conducts with both children and adults, can be understood

in these terms, as an attempt, not only to acquaint individuals with different foods and a variety of flavors but to provide them with the training and experience by which they can identify “good” foodstuffs.

While “good” primarily refers, in Slow Food’s analysis, to the quality, taste and flavor of food, the movement also emphasizes the settings in which food is prepared and consumed. Thus, defenders of Slow Food not only deride the quality of “fast food” but the ways in which such food is designed to be eaten, mindlessly, quickly and, often, in isolation from others. Thus, along with the pleasure of “good” food, slow food stresses the pleasure of conviviality or commensality, the joy of sharing food in leisurely company with others. Local chapters of Slow Food are called “convivia” (from the Latin for “feast” or “banquet”) for this very reason.

In upholding the enjoyment and pleasure of “good” food, defenders of Slow Food seek to counter the asceticism that, they believe, characterizes both much of Christian society and traditional leftist politics, wherein the pleasures of eating are often derided for being either sinful or bourgeois (Petrini 2001, 2005). The approach to pleasure embodied in Slow Food hearkens back to the hedonic philosophies put forth in ancient Greek thought and, in particular, the position defended by Epicurus and the Epicureans. For Epicurus, happiness, understood as pleasure, represents the ultimate and highest intrinsic good in life, and so, he argues, we should strive to experience as much pleasure in life as is possible (Epicurus 1964). In promoting the pursuit of pleasure, however, Epicurus does not advocate profligacy or base hedonism, arguing that indulging in too many physical pleasures will ultimately result in excessive pain. Rather, Epicurus maintains that the “good life” is ultimately a life of tranquility, attained by pursuing simple and modest pleasures, including those of good food and friendship.

Proponents of Slow Food construe of pleasure and the pursuit of pleasure in terms similar to those found in Epicurean thought. The pleasures of food and company are extolled as central features of the “good life.” Such pleasure, however, should not be pursued to excess. Borrowing a notion from the

Renaissance humanist Bartolomeo Scappi, figures in Slow Food like to speak of “*honest voluptate*” or “sober pleasure” (Petrini 2009). This is a pleasure that, in contrast with gluttony, is aware of its limits and is pursued in moderation.

Parallels can also be drawn between the vision of the “good life” put forth in Slow Food and that defended by Aristotle’s virtue ethics (Aristotle 1999). Like Epicurus, Aristotle maintains that happiness or eudaimonia is the end of life. For his part, Aristotle argues that such fulfillment can be attained by practicing the virtues, habitual traits of character, that, avoiding excess and deficiency, adhere to the “golden mean.” As does Epicurus, Aristotle rejects a life of pure hedonism which he likens to a life for “grazing animals” (Aristotle 1999). Nevertheless, Aristotle does not advocate asceticism, maintaining that physical pleasure is a critical ingredient of the “good life.” Such pleasure, however, must be pursued in moderation and the relevant Aristotelian virtue as regards the pleasure of food is temperance. Likewise, Aristotle also maintains that friendship is a central feature of the good life.

In promoting the value of pleasure, Slow Food nevertheless seeks to counter the elitism and gourmandism that they believe marks that tradition, arguing that “the right to pleasure” is one that is universally shared and open to everyone (Petrini 2009). Despite their reference to the notion of “rights,” however, Slow Food does not appear to have any fully developed sense of political rights, and at best, the “right to pleasure” can be understood as a right in the negative sense. When alluding to rights, Slow Food seems to conceive of them more in terms of consumer rights, as opposed to civil rights, and this may explain the organization’s reluctance to engage in and seek substantial political and economic reform.

Clean food. As Slow Food has evolved, its concerns have broadened such that its initial focus on good food and gastronomic pleasure is now accompanied by an interest in the environment and environmental issues. So, along with “good” food, Slow Food promotes food that it defines as “clean” (Petrini 2005). This is food that is produced and grown sustainably, in ways that protect and respect the environment, and is

prepared in ways in which processing is as limited as possible. For defenders of Slow Food, there is a close connection between “good” and “clean” food as food that is “clean” often tastes better.

In the estimation of Slow Food, judging whether food is “clean” requires scientific expertise, but they generally believe that the use of chemical pesticides and fertilizers should be avoided, that intensive, highly industrialized modes of agriculture should give way to traditional farming practices and techniques, and that local plant varieties and breeds should be given preference over monocultures and standardized varieties and breeds. Slow Food also opposes the use of genetically modified organisms. Slow Food is not opposed to the transportation of food but argues that the environmental implications of food transport should be kept in mind when determining whether food is “clean” or not.

In combining their interest in the flavor of food with its environmental impact, Slow Food likes to describe their culinary philosophy as “ecogastronomy,” a pursuit of gastronomic pleasure that is informed by environmental awareness (Petrini 2005). Given the principles of “ecogastronomy,” the follower of Slow Food is not necessarily going to limit themselves to eating organic food or practicing locavorism. While organic food may be “clean,” it may not be “good,” and it is not clear, according to Slow Food, that food must be organic to be “clean.” When it comes to locavorism, Slow Food does promote local food varieties and traditions as evidenced by its Ark of Taste and Presidia programs (Irving 2008; Malatesta et al. 2005). However, Slow Food’s interest in local foods is not motivated by concerns regarding “food miles” or the environmental impact of transporting food great distances but by the impact that the loss of local foods, due to homogenization and standardization, has on gustatory pleasure. In fact, many of Slow Food’s projects and initiatives involve seeking broader, international markets for local products.

In discussing Slow Food’s notion of “clean” food, it is perhaps appropriate to point out that the organization has little to next to nothing to say about issues concerning animal rights or animal

welfare. While Slow Food espouses a universal “right to pleasure,” this right is not understood as extending to nonhuman animals. And while Slow Food may be critical of certain practices in regard to animal husbandry, factory farming, CAFO’s, etc., their concerns are more a product of the quality of such foods, their “goodness” in their terms, than they are response to any animal pain or suffering they may cause.

Fair food. As with “clean” food, Slow Food’s defense of “fair” food has evolved over time as the movement has grown. According to Slow Food, “fair” food is that involves equitable and proper remuneration for farmers, farm workers, and food producers (Petrini 2005). In this regard, Slow Food’s interest in “fair” food parallels the recent fair-trade movement. When discussing “fair” food, leaders of Slow Food often refer to what they call “virtuous globalization” (Petrini 2009). As noted above in reference to locavorism, Slow Food is not, in principle, opposed to the transport of food over long distances and welcomes globalized food markets. It is critical not of globalization itself but of tendencies in globalization toward standardization and homogenization.

The Slow Food movement is not inherently anti-capitalist and much of its work focuses on securing markets for what it believes are high-quality foodstuffs. It believes it can achieve this by, on the one hand, educating consumers and raising awareness in them, through programs such as “Taste Workshops” and food fairs, about “good” food and, on the other hand, by forming cooperative networks among small-scale producers. In its activities, Slow Food eschews tactics such as boycotts and direct action as utilized by groups like José Bové’s Confédération Paysanne.

In summary, the ideal eater for Slow Food is someone who possesses a series of virtues. They appreciate good food in moderation while at the same time being cognizant of the impact that their food choices have on the environment and, guided by a sense of justice, respect the rights of those involved in food production.

Criticisms. This somewhat eclectic collection of values and virtues has led some to criticize Slow Food of being guilty of certain contradictions (Chrzan 2004; Donati 2005; Gaytán 2004;

Jones et al. 2003; Labelle 2004; Laudan 2001; Lotti 2010). Some critics argue, for example, that there is a conflict between Slow Food’s promotion of “good” food and its concern for “clean” food insofar as raising the demand for certain products is environmentally unsustainable. Similarly, some critics maintain that while Slow Food avows that pleasure is a universal right and that food should be “fair,” the movement’s reluctance to demand substantial political and economic reform opens the group up to charges of elitism, especially insofar as the typically expensive foodstuffs it seeks to promote remain beyond the reach of many consumers. It would appear that the future success of Slow Food depends on its ability to respond to these criticisms and articulate a coherent, ethical vision.

Introduction

Soil is a key component to any successful agricultural operation, serving as a growth medium for plants and providing water and essential nutrients. It is also a highly precious commodity that can be quickly degraded but takes a very long time to form. Soil formation depends on five important factors: climate, living organisms, topography, parent materials, and time (Jenny 1941). Time is the controlling factor for all the other variables, as it allows for parent materials to weather and organisms to further modify those materials into soil. It often takes thousands of years for a soil to reach its maturity because of the slow processes of physical and chemical weathering of a given parent material. For example, soils that form along rivers and streams are sediments deposited as a result of multiple flood events over time. Each flood event may only deposit a centimeter or two of sediment at a time, therefore potentially requiring hundreds of flood events to have enough material for a deep soil profile. After the sediments are deposited, they undergo transformations to form soil horizons with the help of various soil micro- and macro-organisms, including bacteria, fungi, and earthworms among others. These organisms work at such a small scale, and under very specific

temperature and moisture conditions, that it takes decades before their impact is clearly visible.

Soil and Agriculture

Agriculture is one of the leading agents in global soil degradation due to its influence on soil fertility and soil erosion. Soil quality, a measure of physical, chemical, and biological properties of soil, is frequently degraded as a result of agriculture because of practices such as the use of artificial inputs of nutrients, removal of native vegetation, and destruction of soil physical properties through extensive cultivation (Kibblewhite et al. 2008). In terms of soil fertility, many intensive agricultural systems deplete the soil of its natural nutrient supply and thus soil must be supplemented with artificially produced fertilizers. A prime example is the Corn Belt region of the United States, where the majority of farmable land is populated with monoculture corn. Corn requires large amounts of nitrogen to be able to grow properly, and the soil does not hold enough naturally for the plant's growth cycle, especially after years of solely corn being planted. To maintain yield, farmers alter the soil environment by adding nitrogen fertilizers, either artificial or natural, to the soil at various points of the year. Situations such as this are an example of human-induced nutrient depletion, which are common in countries with large, commercial agriculture systems. Eventually, overuse of the nutrient stocks in the soil can have negative impacts on global food security and the potential to use sustainable agricultural practices (Tan et al. 2005).

Poor management of soil resources has also triggered massive erosion events in different parts of the world throughout history. One of the most memorable in the USA is the Dust Bowl. This was a direct result of the combination of poor farming techniques and an extensive drought, lasting through the early 1930s, that created unusually dry conditions across the country. At that point in time, farmers across the central United States were trying to grow wheat and corn with dryland farming methods, leaving large parcels of

land bare during the rainy season, from April to September, in order to allow the soil to absorb that water in preparation for a cropping of winter wheat. But without surface cover in the summer, the soil was very susceptible to wind erosion, and the dry conditions, compounded by the drought, led to the Dust Bowl (Phillips 1999). A more recent example of soil erosion on a massive scale can be found in the Loess Plateau in eastern China. Thousands of tons of soil have been eroded by wind and water from cultivated lands within the Loess Plateau. This is often a direct result of poor soil management techniques, including a destruction of native vegetation, and cultivation of land on steep slopes (Shi and Shao 2000).

Global Relationships Between Soils and Agriculture

Soil is inherently different across the globe because of the way it is formed. The different climates, geologic materials, and topography across the planet interact to form specific types of soil in each corner of the world. Ramankutty et al. (2008) used remote sensing and agriculture inventory data to map where different types of agricultural land, cropland and pastureland specifically, were located on a global scale. When those images are overlaid with a global soil distribution map (USDA-NRCS 2005), there is a distinct relationship between those areas with a high percentage of cropland as mapped by Ramankutty et al. (2008) and the areas where Mollisols are found. Mollisols are one of the twelve soil order classifications within USDA soil taxonomy mapped across the world and are organic rich, highly fertile soils often associated with native grassland vegetation and, in modern times, intensive agriculture. The primary exception to this global pattern is the country of India, which has a high percentage of cropland but very few, if any, Mollisols. Immense population numbers in this region, and others like it, are likely encouraging residents to farm soils that are not properly suited for intensive agriculture in an effort to provide food to their peoples.

From an economic standpoint, agriculture is vitally important to countries all over the world. Particularly in those areas with highly fertile soils, a lot of money is spent producing food, and the trade in and out of those areas is also heavily based on agricultural goods. In the USA, farms produced over \$390 billion worth of crops and livestock and exported \$141.3 billion of agricultural products in 2012 alone (Klobuchar 2013). Similar numbers can be found in multiple other places, with the higher economic values typically coming from more developed countries that have access to new technologies, machinery, and artificial fertilizers.

Agricultural practices vary widely between different global regions and between developed and developing countries. In developed or newly industrialized countries, including the USA, the United Kingdom, Brazil, and China, agriculture is highly mechanized as farmers have better economic access to machinery, inputs, and other agricultural technologies to be more sustainable. Developed countries have also spent years and millions of dollars developing different genetically improved versions of basic crops, such as corn, wheat, and rice, to allow for more efficient use of pesticides and fertilizers. In developing countries, agriculture is often practiced at the subsistence level with fewer economic inputs into agricultural production. Inputs and mechanization tends to be reserved for export cash crops rather than crops grown for local consumption, and farm sizes tend to be smaller overall. In many developing regions of the world, the soil is likely to have lower levels of natural fertility, and the climatic conditions may not be optimal for growing many key foodstuffs. Small-scale farmers in areas without industrialized agriculture have developed many useful and efficient techniques for maintaining soil health and productivity, including crop rotation and the use of green manures and cover crops (Prasad and Goswami 1992). In many ways, agriculture in developing countries actually protects and appreciates the soil more than in developed countries because the peoples' everyday lives depend on the food they grow as individuals and the soil that enables them to produce it.

Local and Traditional Knowledge of Soil

Indigenous populations often have a vast knowledge of their surroundings and have even developed systems of classification for the natural resources they use on a daily basis. This is no different for soils. Ethnopedology focuses on local populations' knowledge of soils, including their management, classification, and use of this resource. Studies around the world have documented soils knowledge from local populations, especially those regions known to be centers of origin for modern plants (Barrera-Bassols and Zinck 2003). These studies have shown that indigenous populations often have a large collective knowledge about soil and frequently have developed their own classification systems. By comparing indigenous knowledge of soils to Western scientific knowledge, scientists have shown that local classification systems often document important features that are similar to the modern classification systems used to map soils across the world. By making records of these native knowledge bases, researchers are also collecting information on the native languages used in these areas and how words are developed for and assigned to soils (Barrera-Bassols and Zinck 2003).

Indigenous soil knowledge is often based on spiritual and cultural beliefs, but in many places, including Latin America, local people have also developed very specific descriptions for soils. Winklerprins and Barrera-Bassols (2004) conducted a study within three sections of Latin America's primary agricultural areas to catalog the knowledge base of the local people in regards to soil. In Middle America, Mexico and Guatemala specifically, the local Nahua people hold a strong link between the "kosmos" and the earth, keeping them spiritually close to the soil. Drawings and glyphs clearly indicate that the people of this region understand how soil works and how it could, and can, be managed. They included information about how soils differed by texture, landscape position, and how well crops like maize would fare in different soils. People of the Andean region were also well versed in soil knowledge. While there is not as much evidence present in the

written history, there is a large amount of physical evidence across the landscape. Farmers in this area terraced and raised their fields, primarily to please the Earth Mother, who would repay them with good weather and high crop yields. Aside from the manipulation of the land, these peoples also established a well detailed classification system that includes texture and color as primary indicators. Amazonia, the final region observed in the study by Winklerprins and Barrera-Bassols (2004), does not have as clear of an ethnopedologic record. Most of the information is more modern because of the lack of pre-settlement agriculture that is still occurring in its original form. Those peoples that are still indigenous use soil color, texture, and porosity to categorize soil quality and link these properties to the relief and sediments of the land. Almost all of the descriptors used by local people are also incorporated within modern mapping and classification methods. Based on these examples, it is clear that soil has been studied and respected for a long period of time, and even without structured science, soils are grouped to be used in the best possible way.

Soil Productivity and Agriculture

Although definitions of soil quality vary widely, most focus on some aspect of the soil's ability to function. Poor quality soils are unable to provide adequate nutrients and water to plants, and thus it is very important to measure and track soil quality within agricultural landscapes. Soil quality is measured in a variety of ways and at multiple scales. Indicators of soil quality, also known as soil health, include physical, biological, and chemical properties of the soil. Typically these properties are dynamic within the soil, meaning they change as the land use and management of the soil changes. Key measures of soil quality include: organic matter content, infiltration of water, aggregate stability, pH, microbial biomass, nitrogen content, bulk density, and availability of nutrients, among others (Karlen et al. 1997). To properly measure soil quality for agriculture, these properties are only measured within the

surface of the soil, usually to a maximum depth of about 30 cm. One of these properties can have dramatic impacts on another, and they often work together to keep the soil functioning at its best. For example, aggregate stability will be at its highest levels when the soil also has high levels of organic matter and microbial activity as these characteristics work to help hold the different soil particles together to withstand changes within the soil (Karlen et al. 1997).

Unfortunately, agriculture is one of the leading destroyers of soil quality globally. Soils are vulnerable to erosion as multiple passes are made across a given field to prepare the seed bed, plant the crop, fertilize the crop, manage pests, and harvest, all conducted with heavy machinery where it is available. Heavy machinery also subjects surface horizons of the soil to compaction, reduced organic matter, porosity, and microbial activity, less stable aggregates, and larger, less organized structural units. As soil quality is degraded, direct environmental impacts include increased erosion and leaching of nutrients (Karlen et al. 1997). When soil quality is maintained, improved soil fertility leads to increased agricultural yields and soils that are less susceptible to erosion, keeping them in place for further use.

A second, but equally important, component of soil for agriculture is soil fertility. This component of soils is its ability to provide essential nutrients and water to the plant being grown and is directly related to soil quality. Soil fertility relies on the amount of each nutrient present within the soil, the form in which the nutrient is present, or whether it is plant available, and the soil pH, one of the properties measured within soil quality. There is also some influence played by the texture of soils. Soils with more clay present will typically hold more of certain types of nutrients like potassium and calcium in comparison with sandier soils. pH is the primary soil property that will determine how much of each nutrient will be available within the soil (Fernández and Hoef 2009). Different nutrients are solubilized and made plant available in acidic versus alkaline soils. Specifically, acidic soils often have high concentrations of iron and aluminum, either of

which can create toxic environments for plants, while alkaline soils typically have high concentrations of phosphorus, potassium, and sulfur. There is a small zone around the neutral pH values that provides optimal levels of the plant essential nutrients, primarily nitrogen, phosphorus, and potassium. Other measures of soil quality typically stabilize soil pH creating a link between a high quality soil and high levels of fertility and agricultural productivity.

A variety of approaches are used to manage soil fertility including amending the soil with fertilizers (artificial or natural) or adjusting soil pH to balance availability of different plant nutrients. Different places in the world require different techniques to manage fertility. Naturally fertile soils need minimal adjustments, except for when they are farmed intensively, as in developed countries. In such cases, artificial fertilizer is often applied to supplement nutrients removed from intensive harvests (Kibblewhite et al. 2008). Regions with low levels of soil fertility, such as the tropical rainforest, often have to adopt other techniques to try and raise the nutrient level of the soil, including slash and burn agriculture. Slash and burn is the process by which the native vegetation, typically trees, are cut down and then burned. Ash from the burned vegetation adds some nutrients to the surface horizons of these nutrient-poor soils. The boost in fertility lasts only a few years at which point the farmer must repeat the process on a new plot of land, allowing the formerly cultivated plot to return to native vegetation. After several years, the native vegetation will have started to reestablish itself, and the cycle can begin again. Soils with acidic pH values can also be adjusted by adding liming substances to bring the value to a more neutral position, but it is very difficult to adjust alkaline soils downward. If necessary, sulfur compounds can be added to lower pH values (Fernández and Hoefft 2009). Economic development also influences the degree to which farmers are able to address soil fertility problems. Farmers in developed countries are typically more financially able to make artificial adjustments to the soil, while farmers in developing nations are often forced to find alternative, more natural ways of dealing with poor soil

fertility. Although products like lime and artificial fertilizers are more accessible to farmers in developed countries, access is increasing globally (UN-FAO 2012).

Soil Conservation and Management

There is a long history of different societies attempting to conserve and manage their soils. This is particularly apparent in Latin America where societies have dramatically changed the landscape to protect their soils. Indigenous populations created elaborate systems to irrigate their crops and to grow crops on the steepest of hillslopes. Populations living in the Andes, including the Incans, made some of the changes that have lasted the longest, including terraced hills and raised fields (Winklerprins and Barrera-Bassols 2004).

To date, some of the best examples of soil conservation come from developing countries because they are less able to artificially amend the soil and because, often times, the soils in these regions are more susceptible to major issues like erosion and nutrient leaching. One of the primary ways to enhance soil productivity, improving both soil quality and fertility, is the use of green manures, also known as cover crops. This technique uses a secondary crop, such as sunnhemp, mung bean, cowpea, and wheat, to provide nutrients and organic matter to the soil outside of the growing season. Leguminous cover crops are often chosen to help improve soil fertility because of their natural ability to fix nitrogen from the atmosphere and release it in a bioavailable form into the soil. In Asia, where rice is the common cash crop, farmers use cover crops to help supplement the nitrogen in the soil because rice requires a lot of nitrogen during its growing cycle (Prasad and Goswami 1992). The type of green manure grown will depend on the region of the world being farmed. In addition to acting as a natural source of nutrients to the soil, these plants will also provide cover to the soil during a time it might normally be left exposed. As a result, erosion rates will likely be lowered in these fields. Green manures may also positively impact

physical characteristics of soil that are important soil quality indicators. By maintaining roots within the surface of soil, this secondary crop acts as a source of organic matter, provides food for the microbes that live within the soil and, depending on the crop, breaks up compacted layers within the surface soil. After the cover crop has reached maturity, it can either be harvested as a second cash crop for the year, used as animal feed, incorporated into the soil, or mulched. Mulching these crops will further improve soil properties by protecting the soil from erosion, increasing organic matter content, and maintaining soil moisture within the surface of the soil (Lal 1989).

Crop rotation is another beneficial soil management technique. Different crops have substantially different nutrient requirements. Rotating between crops draws down soil nutrient reserves in different ways and, depending on the crop, may even help to replenish soil fertility. Corn and rice, in particular, have extremely high nitrogen requirements. In the central United States, where corn is the primary crop, soil nitrogen levels are very low. Farmers in this region often choose to rotate corn with a legume, such as soybean, to fix soil nitrogen and improve fertility for the following corn crop. Another benefit of crop rotation relates to land preparation as different crops require different levels of preparation to be planted. Rotating crops means that over time fields will require different amounts of cultivation before planting, applications of fertilizer, and different harvesting techniques. In the case where the field requires fewer passes with machinery, the physical characteristics of the soil, such as bulk density and structure, may be able to recover towards a more natural state. Overall, rotating crops will change how the soil is managed from a physical perspective, which will keep them more productive for a longer period of time (Prasad and Goswami 1992).

A final common management technique is conservation tillage or no-till systems. While these systems are common in some developing countries due to a lack of heavy machinery, conservation tillage is gaining popularity in Western countries as soil erosion is recognized as a major

issue by more and more people. The goal of conservation tillage is to increase the amount of residue cover left on the field after harvest in order to prevent erosion, increase soil organic matter, and improve soil moisture retention, and decrease fertilizer applications. In mechanized agricultural settings, this is done by reducing the number of passes across a field using tillage implements (Lal 1989). Conservation tillage ranges in application from leaving just a small amount of residue cover to more than ninety percent residue cover on the field, which is then labeled as a “no-till” agricultural system. These types of tillage systems are highly beneficial to soil and agricultural health. Globally there is data showing that reduced tillage and increased vegetative cover decreases erosion. Both of these factors protect the soil from being detached and moved by both wind and water. Second, the physical properties of the surface soil will be much improved under conservation tillage. Soil structure, a soil quality indicator, will improve as biological activity increases, and compaction is lowered by the removal of machinery. Finally, conservation tillage will often have positive impacts on soil fertility. Residue cover of the soil will maintain a consistent soil moisture and temperature regime for longer, making it easier for plants to establish themselves. It has also been shown that nutrients are more available within the root zone of plants as a result of conservation tillage, even in low fertility soils, such as those found in Brazil and Nigeria (Lal 1989).

Summary

Soil is one of our planet’s most important natural resources, both in terms of ecosystem health and agricultural production. Yet, poor soil management leads to declining soil fertility and wide scale erosion, threatening the health of this valuable resource. Various soil physical, biological, and chemical properties impact soil quality. Management strategies focused on soil quality improves soil fertility and agricultural productivity. The importance of soil management has been recognized by many cultures over time and can be recognized today by the different indigenous

classification systems that exist around the world. These classifications are strikingly similar to those classifications of modern soil science. As knowledge of agriculture's impact on soil increases, so do the number of management techniques available to help protect and maintain soil. Management techniques may vary globally, but their overall focus is the same, focusing on improving key indicators of soil quality. Good management of soils in agricultural settings protects soils from erosion and leads to high quality, productive agricultural systems that can support human populations in different environments around the world.

South Asia and Cow Protectionism

James Stewart

University of Tasmania, Hobart, TAS, Australia

The cow is viewed as a creature of special importance among several religious and cultural traditions in South Asia. Cow protectionism is

practiced in India, Nepal, Burma, and Sri Lanka. The veneration of the cow also traverses religious denomination and cows are valued within both Buddhist and Hindu communities. The origin of cow protectionism in South Asia derives to a large extent from a sense of religious obligation, though prudential reasoning has also played an important role in the promotion of cow welfare.

Among many Hindus in India, cows are regarded as sacred objects that should not be interfered with, let alone slaughtered. The slaughter of cows is outlawed, or severely limited, in most states in India, and there are severe penalties for those who unjustifiably kill them. There are even some historical instances where cow slaughter was made a capital offense (McLane 1977). The penalty in modern Indian states is, of course, much less severe.

This special treatment of cows has some textual justification in the *Vedas*, an ancient corpus of sacred texts that have shaped modern Hinduism (Alsdorf 2010). Some parts of the *Vedas* have been dated from 1700 to 1100 BCE; cows have played an important role in the Indian subcontinent for a long time. This concern continues on into the modern era. Indeed, issues around cow protectionism represented an important part of the Indian independence movement (Van der Veer 1994). Even so, the issue of cow protectionism is nuanced. Yet the politicization of cow protectionism, and the idea that cows cannot be slaughtered, is a more recent phenomenon in India that stems in part from the Indian independence movement (Jha 2002).

In Hinduism, the justification for the unique protection of cows, over and above other animals, is attributed to their association with Hindu deities or their special association with the sacred feminine. In general, the bovine is of spiritual significance in Hinduism. Shiva, one of the most important and powerful deities in the Hindu pantheon, has Nandi the bull as a vehicle (Cush et al. 2008). Kamadhenu, the mother of cows and the sacred provider of milk, is a deity of some religious significance in India (Bonney and Donniger 1993). Another example of this is the deity Krishna, an avatar of Vishnu – another deity

of high importance in modern Hinduism – who was once a cow herder (Van der Veer 1994). Cow products are frequently used in a variety of sacred ritual ceremonies (Van der Veer 1994; Bastin 2002; Fuller 2004).

Nepal, being a primarily Hindu nation, also maintains a strong tradition of cow protectionism. Cow slaughter is illegal in Nepal and there are penalties for killing cows and eating beef. Historically, these penalties have been very severe. For example, in 1805 King Rana Bahadur Shah made a decree that those who are found to have killed a cow must be executed by state officials (Michaels 2004). Subsequent laws in Nepal involved the execution and violent torture of individuals who transgress the ban on cow slaughter (ibid). One torture method involved the violator being forced to eat their own flesh before receiving capital punishment (ibid). These laws were later relaxed, and over the years, fines and/or imprisonment have been implemented as forms of punishment.

Buddhist South Asian nations also maintain popular cow protectionist movements. Despite the fact that Buddhist texts tend to treat sentient animals as beings of equal moral worth, Sinhalese (Sri Lankan) Buddhists (Stewart 2015) and Burmese Buddhists (Braun 2013) often treat cows with special attention and importance. In recent years there has been a strong push by interest groups to have cattle slaughter outlawed altogether. An explanation for cow exceptionalism is therefore warranted. One answer is that Sri Lanka and Burma are in proximity to India and therefore the exchange of cultural practices are to be expected. In Sri Lanka, many Buddhist Sinhalese practice Hindu rituals and believe in the Hindu pantheon (Gombrich and Obeyesekere 1988). Hindu practices are therefore integrated into the Sinhala Buddhist religious life. There are also special and unique religious cults in Sri Lanka – cults that also have their origin in India – in particular the Kiri Amma cult (Obeyesekere 1984). Another explanation is the preexisting textual authority for cow exceptionalism, and some Buddhist texts do imply that the cow is of special significance (Norman 2006).

In Sri Lanka, there is also a sizable Hindu Tamil population, usually Saivite in orientation, that worship the cow in the manner normally accepted in mainland India (Bastin 2002). Cow protectionism in Sri Lanka is therefore practiced in multireligious, multiethnic ways.

In Burma, as in Sri Lanka, the cow protection movement stems in part from a deep respect for the cow as a beast of burden. The cow should therefore be protected as a matter of respect for its hard work and sacrifice (Braun 2013). This concern stems in part from the fact that the Burmese and Sri Lankan economies have been historically agricultural. There is a strong discourse in Sri Lanka (Stewart 2015) and in Burma (Braun 2013) that the cow is a provider of milk that helps sustain and grow the nation. Therefore, the mystical, religious motive for cow protection is also mixed with prudential awareness of properly maintaining and cultivating a strong cow population.

Cow protectionism has occasionally led to ethnic conflict. In India this ethnic conflict has typically occurred between Hindu and Muslim communities (McLane 1977; Van der Veer 1994). Hindu nationalists have seen Muslim cow slaughter practices as an insult to their religious convictions. This has been complicated by the fact that Muslims sometimes regard cow slaughter as a religious duty during the Bakr Id Festival (McLane 1977). Over the years, this tension has led to communal rioting, assaults, and the killing of a number of Muslims. In Sri Lanka and Burma too, Muslims have borne the brunt of much cow protectionist animosity (Braun 2013; Stewart 2013, 2014, 2015). In Burma, when cattle slaughter has been allowed, it has almost exclusively been a practice conducted by Muslims (Spiro 1982). This is also the case in Sri Lanka (Gombrich 1991). In these countries, conflict over the treatment of cows has also resulted in communal rioting as well as individual acts of violence. Christians have also been targeted as a result of this violence, as well. In Sri Lanka, monks have even committed self-immolation in protest against these actions (Stewart 2015). Such is the seriousness of the cow protectionist movement.

Historical Considerations

The origin of cow veneration in South Asia must start with an examination of views found in the *Vedas*. These ancient texts now form an integral part of modern Hindu religious life and have shaped antecedent religious movements in the Indian subcontinent. The *Vedas* make it clear that the cow is of special religious significance and is construed as one of the most divine animals (Alsdorf 2010). Yet these texts do not instruct the believer to abstain from killing them. On the contrary, according to the *Vedas*, the very fact that the cow is worthy of veneration and spiritual respect makes it an ideal object of ritual sacrifice for the gods (Alsdorf 2010; Lipner 2010). Things change with the introduction of the *Manusmṛti* (*Law Codes of Manu*), another important document that has shaped modern Hindu legalism. This text is found within the *Dharmasastras* and is variously dated to the second century BCE to the third century CE. The *Manusmṛti* represents a shift from the cow as an object of sacrifice to a creature that should be protected from sacrifice. Both these incongruous views are present within this text (Alsdorf 2010).

The *Bhagavad Gita* (fifth to second century BCE), a cornerstone of modern Hindu religious life, has been interpreted as a document that prescribes nonviolence and cow protectionism. Although the *Bhagavad Gita* does not explicitly endorse cow protectionism (Brown 1964), it has been interpreted to be so in light of its association with the deity Krishna and its apparent endorsement of nonviolence, a doctrine known as *ahimsa* within many South Asian cultures. This interpretation of the *Bhagavad Gita* is particularly clear in the case of the Hari Krishna movement (Rosen 2004).

General endorsements of cow exceptionalism within these sacred texts led to the rise of cow veneration and cow protectionism within pre-modern Indian religious movements that were based upon texts such as the *Vedas*. There was also a motive to protect cows as a result of ethnic and religious competition. Abstention from beef eating and an increased interest in cow protection became important for many followers of these

native religions as Muslims invaders began to occupy Indic lands during the medieval period (Lipner 2010). This animosity led to the rejection of beef eating as it was perceived to be a foreign practice associated with the Muslim invaders (McLane 1977; Lipner 2010). This, in turn, led to the increased recognition of the importance of cow protectionism.

The relationship between cow protectionism and ethnic and religious politics becomes especially clear during the period of the Indian independence movement. Mahatma Gandhi, a key figure and widely respected leader in the independence movement, regarded cow veneration as a key part of the Hindu religious life (Ven der Veer 1994). This was not, however, compatible with his religious pluralism as Muslims continued to slaughter cows in accordance with their own religious traditions. Indeed, the Hindu-only faction of the Indian independence movement used Muslim cow slaughter practices as a mechanism to preach the view that the new India should be a nation that excluded Muslims. Gandhi attempted to remedy this through his concept of *satyagraha* – he believed that the Hindus should win over their Muslim compatriots through mutual love and understanding (Van der Veer 1994).

Tensions between Hindus and Muslims over the issue of cow slaughter have nonetheless exploded at various times both during and after Indian independence. In particular, anti-Muslim rioting was especially prevalent in 1893 (McLane 1977). In part, Hindu anger was fueled by the British colonial tendency to try and foster an artificial pluralism by protecting Muslims and then consequently demanding that Hindus adopt an interpretation of the Hindu religion in which cows were not deemed to be sacred creatures (Van der Veer 1994). It should also be noted that Hindu nationalists enforced cow protectionism on other more moderate Hindus, and this led to the shaming and punishment of Hindus who were less concerned with it (McLane 1977). For example, Hindus were punished by local councils for selling cattle to Muslims, and in some places, a tax was enforced for the purpose of buying cows from butchers and abattoirs (McLane 1977). Nonetheless, cow protectionism

continues to be a source of conflict into the modern period (McLane 1977).

Cow protectionism has been a crucial part of Indian politics. The Arya Samaj movement has been instrumental in developing and spearheading the cow protection movement in India (Van der Veer 1994). Another example is Indira Gandhi's Congress Party's electoral symbol which was an image of a cow suckling a calf (McLane 1977). Finally, Hindu nationalist concerns with cow protectionism are also associated with Hindu food ethics and meat eating.

In Sinhala Buddhist Sri Lanka, cow protectionism also has strong historical roots. As mentioned above, there are some Buddhist texts of importance to Sinhala Buddhists that endorse the cow as a creature of special importance. The *Sutta Nipata*, for example, celebrates the cow as an important creature (Norman 1984), and in other *sutras*, the cowherd is used in positive terms as an analogy for those who cross over the river of suffering to the shores of enlightenment successfully (Buswell and Lopez 2014).

We learn from the records of colonists that Sinhala Buddhists were also concerned with exclusive acts of cow protection and repudiated the consumption of cow flesh. During the Portuguese occupation (1505–1658), Pieris observes that Sinhala Buddhists would not eat cows and attributes this to a reverence for the animal adopted from the Indian Hindus (Pieris 1920). Likewise, Robert Knox, a British sailor who was a prisoner of the Kandyan Kingdom during Sri Lanka's Dutch occupation (1656–1796), also noted that Sinhala Buddhists refuse to eat beef, revere the cow, and in fact regard foreigners who consume cow flesh with derision (Knox 1958). This concern over cows in Buddhist Sri Lanka is also strongly connected to questions of Buddhist food ethics and questions around meat consumption.

In modern Sri Lanka, cow protectionism continues to be of high importance. For example, the All Ceylon Buddhist Congress in 1985 adopted a resolution that, among other things, urged Buddhists to give up eating beef because bovines help the rice farmer (Bond 1992). As in India, the cow protection movement is highly politicized and has

led to tension with the indigenous Muslim community. Rioting between Sinhala Buddhists and Muslims has been a fact of Sri Lankan history both before, but especially after, independence (Jayawardena 1970; Kannagara 1984). These anti-Muslim riots often stem, at least in part, from animosity born from the Muslim practice of slaughtering cattle. Nonetheless, because Sinhalese Buddhists cannot kill cattle, there continues to be a demand for beef that is met by Muslim butchers (Gombrich 1991). This is the case even though Sinhala Buddhist nationalists continue to maintain a campaign to shut down Muslim abattoirs (Stewart 2015). Violence against Muslims as a consequence of strong views about cattle slaughter continues on in the present time (*ibid.*).

In Burma, similar concern over cow protection is evident. As in the case of India and Sri Lanka, this concern has also led to conflict with the local Muslim population. In ancient times, cows were held in high regard in Burma because they were associated with agriculture (Braun 2013). Ledi Sayadaw (an important Burmese Buddhist reformer and political agitator) viewed cow protectionism as an important extension of his Buddhist values and used it as a platform to attack British colonists (Braun 2013). In the 1880s he penned a letter urging his Buddhist followers to give up beef eating and take seriously the need to venerate and protect cows from harm.

After independence, Burma adopted measures to ban the slaughter of cattle as a result of legislation instituted by U Nu, a leading Burmese nationalist. In contemporary times, the Muslim minority in Burma has been routinely subject to attack by Burmese nationalists, again, in part stemming from animosity over their practice of cow slaughter.

Motives for Cow Protectionism

The central motives driving cow protectionism in South Asia are (1) an ethical concern over the welfare of cows, typically born from religious convictions; (2) prudential arguments for caring for the cow, such as the fact that cows support the

wider community with their products; and (3) cynical exploitation of underlying concern for cows for political gain.

The first motive of ethical concern for cow welfare is usually religious in nature. In India, the cow is positively compared to one's own human mother. Gandhi, for example, comments that we should venerate the cow out of gratitude for supporting us as we do our own mother (Jha 2002). There is therefore a strong argument that cows should be treated with respect just as our mothers are treated with respect. This analogical argument nonetheless has religious associations because of the spiritual importance of the spiritual feminine in Hinduism. This feminine domain is important since it is the female consort of the gods that provides the male deity with his power (*shakti*) (Fuller 2004). In this way, the spiritual feminine is of moral and religious importance in modern Hinduism. Worship of the cow is therefore connected to the worship of the essence of the main Hindu gods.

As discussed above, the cow is associated with the story of Krishna. Krishna's childhood was based in a pastoral environment and he was often surrounded by herds of cows (Van der Veer 1994). The myth of Krishna also tells us of how he stole milk and curd from cows (*ibid.*). This has led to milk playing an important role in Hindu ritual libations (Smith 1990). Kamadhenu is the more explicit manifestation of the cow as an object of religious veneration. The cosmic deity Kamadhenu, also known as the "mother of all cows," manifested from a great churning ocean of cosmic milk (Bonnefoy and Donniger 1993). She is considered the "source of all prosperity" and plays an important role in the relief of disease and illness (*ibid.*).

It is clear, then, that veneration of the cow in Hinduism is also associated closely with milk and milk products. Indeed, the five products of the cow – cow dung, milk, urine, curd, and ghee (the latter two being derived products) – are important in a number of Hindu rituals. They are particularly important during the Thai Pongal festival. During this harvest festival, painted and decorated bullocks are worshipped and milk libations are made at temples (Gough 1981). When

combined in particular ways, these five products can form a compound that is also considered a reliable homeopathic medical treatment.

As stated above, the cow was once sacrificed as a way to please the gods, but this has since ended under the view that the cow should instead be protected from harm. Despite this, the cow is still associated with religious sacrifice, albeit in a nonviolence way. For example, cows are sometimes given to Brahman priests (Bonney and Donniger 1993), and the release of cows from slaughterhouses is viewed as a religious duty. In this way, the religious ideal of blood sacrifice has been reappropriated toward nonviolent ends.

This reverence for the cow in Hinduism is also exemplified in other creatures including Nandi. Nandi is a bull that acts as Shiva's vehicle (*vahana*). All major Hindu deities have an animal vehicle, and they are of spiritual significance because they act as a gatekeeper between the worshipper and the deity and his consort. Nandi, of course, is a male bull, and this therefore runs counter to the prevailing narrative of the bovine being associated primarily with the feminine. Note also that during religious festivals like Thai Pongal, it is usually bullocks (males) that are worshipped. This illustrates that the importance of the bovine transcends just the feminine, though the feminine is of predominant importance.

Cow protection and veneration in Sri Lanka occupies a similar religious space to India. Hindu Tamil Sri Lankans participate in cow veneration activities in similar fashion to their Hindu Indian counterparts. During Thai Pongal celebrations, Hindu Tamil Sri Lankans also decorate and worship cows. Rohan Bastin has observed that the five products of the cow discussed above are used during religious rituals at Hindu temples in Sri Lanka (Bastin 2002). Indeed, Bastin observes that cow dung is a central part of Hindu ritualism at the Munnesvaram temple in Eastern Sri Lanka and is used to mark the images of sacred deities (ibid). As in India, milk libations play a central role in Hindu Tamil Sri Lankan ritualism (ibid).

Sinhala Buddhists in Sri Lanka also respect and venerate the cow. As discussed by Obeyesekere, this veneration is rooted primarily in concern over the Kiri Amma deity

(Obeyesekere 1984). Kiri Amma means "milk mother" and is also the common name for the patrilineal grandmother. As in India, therefore, there is a strong connection between the domain of the spiritual feminine and the cow (Stewart 2015). The modern cow protectionist movement in Sri Lanka commonly deploys arguments to link respect of the mother with respect for the cow in the same manner as Gandhi discussed above (ibid). Obeyesekere has observed that there are ceremonies and rituals associated with veneration of the Kiri Amma deity that are intended to relieve illness in young children (Obeyesekere 1984). This is because Kiri Amma is isomorphic with the goddess Pattini who is a native deity that cares for young children and cures disease (ibid). There is also evidence that Sri Lankan Sinhala cow protectionists also recognize the Kamadhenu deity, and her icon can sometimes be found in Sri Lanka (Stewart 2015).

In Sri Lanka, Buddhist arguments are also employed in order to justify the protection of cows. These arguments typically center on the need to express compassion (*karuna*) toward other nonhuman creatures (Stewart 2013, 2015). In this way, it is a Buddhist duty to save cows for the same reason that other animals must be saved. However, the exceptional position of cows is in part a result of other religious forces discussed above.

There are also prudential arguments in favor of cow protectionism, though these arguments are almost always linked ultimately to religious consideration. In Sri Lanka, cow protectionist groups have run campaigns to advocate for the better of treatment of cows because they are of instrumental importance in supplying schoolchildren with milk (Stewart 2015). Such campaigns argue that cow's milk is essential in strengthening growing children and that it is important as a way to supplement a human mother's milk (ibid). There have also been arguments that the religious attitude toward the cow stems originally from the pragmatic need to preserve cows due to their economic and agricultural value (Crooke 1912; Jha 2002).

Economic arguments are also evident in the nineteenth century where educated Indians became aware of the poor condition of Indian

livestock and sought to raise awareness about the need to maintain a healthy dairy industry (McLane 1977). These Indians represented a sector of the Indian Hindu community that were not offended by the Muslim or non-Hindu treatment of the cow but were concerned about cows for other practical reasons. Likewise, the leader of Arya Samaj, Dayananda – an Indian nationalist organization – maintained that stopping the slaughter of cows was important because a living cow would sustain the lives of more people than a dead one would (ibid). These, and other similar examples, illustrate how cow protectionism has not always been concerned with religious motivation, but that there has also been a strong economic and prudential line of thinking when it comes to improving cow welfare in India.

There are also examples of cow protectionism being used as an expedient means to motivate other political campaigns. One example of this is the Kuka Movement in India in the 1870s. Recognizing that their movement had begun to lose its momentum, Kuka leaders attempted to raise awareness by beginning a cow protectionist campaign that targeted local Muslims (McLane 1977).

Conclusion

The cow protection movement in South Asia has strong historical roots that go back to its ancient religious texts. Cow protectionism is most strong in India though it has spread to almost all neighboring countries including Nepal, as well as Buddhist nations such as Burma and Sri Lanka.

The origin of this cow protectionism is often religious and centers on various cults and associations with important deities. In Sri Lanka, this concern also stems from Hindu roots though Buddhism has also had a hand in justifying cow protectionism through wider animal welfare concerns. These same concerns have also motivated cow protectionism in Burma.

In all these countries, cow protectionism is strongly associated with ethnic politics. In particular, Muslim communities have been hard hit by nationalists who seek to expel Muslim slaughter practices from their respective countries.

Nonetheless, not all these arguments stem from religious concern which is the typical source. In some cases, economic arguments are deployed to justify cow protection, and in such cases, there is usually no malicious intent toward Muslims or other ethnic groups. In general, concern over cow protection is often linked to other issues such as animal welfare, vegetarianism, and food ethics.

South Asia and Food

James Stewart

University of Tasmania, Hobart, TAS, Australia

Throughout South Asia, food consumption practices are intimately concerned with motives

related to prudence, such as eating foods that promote better health, but also with more complex religious motives. For example, the view that certain food practices can lead to spiritual pollution is a serious issue in Hindu India. Furthermore, food practices are often governed by wider concerns over the treatment of animals. This, in turn, is frequently motivated by religious sentiment. Despite their divergent religious traditions, Buddhists and Hindus both often reject the consumption of beef because it involves the slaughter of cows, an animal that is widely venerated throughout South Asia. Other matters of ethical significance in modern South Asia include issues around questionable labor practices in the agricultural and animal husbandry sector.

The *Vedas* are a body of sacred texts that have been influential within indigenous Indian religions. In these texts, food plays a prominent role. Food is understood to supply our basic life force (Smith 1990), and there was a view among ancient Indian communities that life force was absorbed through the consumption of food, both plant and animal (Spencer 1996). These views would later be adapted into a more systematic religious movement through the *Vedas* whereby ritual sacrifice, and the consumption of products associated with that sacrifice, would lead to the amplification of the worshipper's physical and spiritual powers.

In the ancient heterodox religious traditions, food consumption is also heavily scrutinized. In the Buddhist *Sutra* literature, the Buddha requires that his devotees adhere to a dietary regime governed by strict moderation (Stewart 2010). The founder of Jainism, Mahavira, likewise implemented religious directives that restricted his followers' diets in a variety of different ways (see ► [Jainism and Food](#)) (Dundas 2003). Likewise, the Ajivikas were famous for their extreme dietary practices, and fasting was considered a viable way of developing supernormal abilities (Basham 1951). The relationship between food practices and religious observances therefore has strong roots in the subcontinent.

Many issues concerning food in South Asia center around arguments that have to do with meat consumption. Vegetarianism, in particular,

is ubiquitously associated with India, as are food consumption practices stemming from traditional medical beliefs. In India, these food consumption practices are pan-cultural and pan-religious (see ► [Vegetarianism](#)). Vegetarianism, for example, finds expression in Hinduism and Jainism. Early Buddhism, though not widely practiced in India, does not directly recommend vegetarianism (see ► [Buddhist Perspectives on Food and Agricultural Ethics](#)). Nonetheless, there is widespread respect for vegetarianism in South Asian Buddhist countries like Sri Lanka and Burma. In some interpretations Sikhism, a religion indigenous to the Indian subcontinent, vegetarianism can be viewed in a positive light. In Nepal, a predominantly Hindu country, vegetarianism is sometimes practiced, though not to the same extent as in India (Levine 1987). The Jains are especially restrictive in that they explicitly view plants as objects of moral consideration and they maintain the view that consuming plants is also a sin (Alsdorf 2010).

This concern over the consumption of plants and animals, however, underscores a general reverence for life that would later provide a basis for the idea of non-violence (*ahimsa*) that would become an important feature of indigenous Indian religions (ibid). It is this concern over non-violence that would be particularly influential in the case of heterodox religions such as Jainism and Buddhism and cause them to adopt stringent food consumption practices. Hinduism has also been concerned with the issue of non-violence, but it is also heavily indebted to the concept of moral and spiritual impurity in a way less obvious in the heterodoxy.

Furthermore, foods of all types are frequently associated with wider issues that have to do with health and body image. In particular, in India, masculinity and virility is associated especially with meat eating (Smith 1990), and this is the case throughout South Asia. These matters also intersect with wider issues about the role of food in medicine, and many traditional medical practices – such as Ayurveda and Unani – require restrictive diets in order to improve a patient's health.

In ancient India, the consumption of food was also critically concerned with a cosmic hierarchy

with humans located at the top (Smith 1990). In this cosmic structure, humans are understood to consume animals and, in turn, animals consume other animals and plants. This structural hierarchy implicitly justifies conventional food consumption practices. Ritual sacrifice also played an important role in the early Vedic religion and often led to special food consumption practices. Ritual sacrifice was primarily about the preparation and redistribution of food through special religious observances. For example, the use of ghee or clarified butter, a product of the cow, is a central part of many Vedic rituals (ibid).

In all these matters, food plays a spiritual role in ancient Indian culture and this importance has been transmitted through to contemporary times. This concern has found its way to surrounding South Asian nations and has subsequently influenced attitudes toward food in those nations as well. Yet within individual cultures and traditions, there is considerable disagreement over the correct way to address fundamental questions about how to settle ethical debates around food consumption practices.

Food Agriculture in South Asia

Agriculture has played a critical part in the development of subcontinental society and culture since prehistory. Rice has been cultivated in the Ganga Plains, for example, since at least the Neolithic period (Singh 2008). Rice has therefore been a staple food throughout South Asia since ancient times. The cultivation of rice has also played an important role in many South Asian cultures and traditions. For example, in Sri Lanka, due to the perceived national importance of rice, the rice farmer is sometimes held up as an exemplary individual whose occupation benefits the whole nation (Stewart 2015).

In Northern India, there is also evidence of wheat, barley, lentils, and peas being cultivated during the Neolithic period (Singh 2008). Various animals, including cattle, were also reared and domesticated during this period (ibid). In later periods, a range of crops were added to the above agricultural staples including mangoes,

plantains, jackfruit, coconut, areca, and other plants native to the subcontinent. Even during the ancient period, there is evidence that a spice trade had developed between India and polities in the Mediterranean. In Sri Lanka, evidence of agriculture has also been present since ancient times, but of particular note are the highly advanced irrigation systems developed during the later Anuradhapura period that were used in the northern dry zones to water large farming areas (De Silva 2008). In the British colonial period, the Sri Lankan (then Ceylon) economy was primarily a plantation economy, and the main export was first coffee and then later tea (*ibid*).

Some scholars have argued that the development of agriculture in ancient India helped support a cultural boom in India that led to rapid urbanization and consequently the development of new religious and philosophical traditions that appealed to a new wealthy merchant class (Gombrich 2006). Such new religions included Buddhism and Jainism.

Greater access to food also influenced other cultural practices, such as the possibility of widespread food donations in the form of offerings to monastic institutions, for example, the ancient Buddhist monastic order. The importance of agriculture may have also played a role in other customary practices, such as Vedic animal sacrifice. The most important agricultural animals were also the most prized animals for ritual slaughter, such as the cow (Crooke 1912; Jha 2002). The killing of these animals demonstrated great devotion to the relevant Vedic god because it was an act that entailed significant financial loss.

In modern times, agriculture in South Asia is associated with other ethical problems such as the use of child labor. In India, children of destitute families have often been involved in unpaid labor activities, the majority of which were concerned with agriculture and animal husbandry (Weiner 1991). More recent studies in child labor continue to reveal that children are primarily engaged in trades associated with agriculture (Burra 2005). Similarly, in Sri Lanka, the predominant form of child labor is in the agricultural sector, primarily farming (67 %) (United States Department of Labor 2014). Again, in Burma, child labor is

also ubiquitously associated with the agricultural sector. In some South Asian countries that rely upon agriculture, child labor laws are often relaxed with a view to better the agricultural sector (Basu and Chau 2003).

In general, labor exploitation in the agricultural and food sector is a major problem in South Asia. Tea cultivation in India and Sri Lanka is ubiquitously associated with problematic labor practices (Biyanwila 2011). In Sri Lanka, tea pickers subsist on an irregular and substandard income due to a lack of government oversight that is only compounded by troublesome legislation that has arguably resulted in Sri Lankan Tamil disenfranchisement (Peebles 2001; Vijayapalan 2015). There are also ongoing child labor problems specific to the tea industry in Sri Lanka.

Therefore, apart from the ethical questions directly related to animal welfare and food consumption practices, there are also wider moral questions relating to human labor that need to be considered in these matters. This has led some to call for a boycott of certain South Asian agricultural products, such as tea, in protest of these inequalities and abuses.

Meat Eating and Vegetarianism in Ancient India

Meat eating and vegetarianism remain key issues when it comes to addressing food ethics in South Asia. The origin of this debate stems from ancient Indian sources (see ► [Food in Ancient Indian Philosophy](#)). Contrary to popular belief, there is little evidence that vegetarianism played a role in ancient Indian religious practices. Some scholars have argued that the *Vedas* endorsed the consumption of meat (Alsdorf 2010; Jha 2002). The *Vedas* were key Indic religious texts that were critical in the formation of early indigenous religions such as Vedic Brahmanism but have also come to shape the modern religion of Hinduism. According to these scholars, the earliest part of this body of texts dates from around 1700 to 1100 BCE, and even here there is a recognition that meat can – and even should – be consumed as a part of appropriate religious ceremony.

Scholars note that the ritual slaughter of animals, and their subsequent consumption, was part of Vedic religious observances (Smith 1990; Jha 2002). There is evidence that the *Vedas* endorsed the idea that meat eating was a natural part of the cosmic order whereby humans dominated the animal world (Smith 1990). Indeed, meat is explicitly stated to be the best kind of food (ibid). The importance of vegetarianism is not made in these ancient texts and does not appear as an Indian value until much later on in the development of Indian religions (Alsdorf 2010). Nonetheless, the slaughter of animals as part of religious observances was a necessarily expensive enterprise and was therefore generally practiced by only the wealthy elite (Spencer 1996).

The later development of the idea of non-violence (*ahimsa*) and its importance as a religious aspiration is first made by non-Vedic/Brahmanical religious traditions, such as Jainism and Buddhism. This attitude of non-violence was thought to apply to animals and this in turn led to the development of vegetarianism as an ethical and spiritual ideal.

Of these latter two religions, only Jainism enforced vegetarianism as a religious duty. The ancient Buddhist texts report that the Buddha refused to make meat abstention mandatory and maintained that certain animals could be consumed under specific strict conditions (Stewart 2010). The Buddha maintained that vegetarianism is an optional activity and that meat may be accepted by monks if they know that it is pure in three ways: that the monk had not known, heard, or suspected that the animal had been killed for him (Harvey 2000; Stewart 2010). It seems that this reluctance to adopt vegetarianism as a mandatory activity was driven by a fear of sectarianism that the Buddha believed would lead to the destruction of Buddhism (Stewart 2010). The Buddha also maintained that an injunction that enforced vegetarianism would be an extreme position that violated his own middle way principles (ibid). This split between Buddhism and Jainism over diet has led to considerable conflict. Buddhist texts maintain that Jains are extremist ascetics, while Jain texts argue that Buddhists are decadent gourmards who do not respect the

ascetic necessities of the monastic life (Ulrich 2007; Stewart 2015; Lang 2015).

Jainism, a heterodox ancient Indian religion founded by the sage Mahavira who was a contemporary of the Buddha, expounded the view that meat eating is a violation of the key Jain ethical principle of non-violence (Dundas 2003). This non-violence principle holds that Jains should not harm any living creature; this can also include plants and microorganisms. This has led some Jain monks to undertake severe practices such as sweeping the ground in front of them so they do not step on small animals and insects and also wearing masks to prevent the inadvertent breathing in, and therefore killing, of tiny insects (Spencer 1998; Dundas 2003). It is therefore unsurprising that Jains are also required to abstain from meat consumption since this necessarily involves the slaughter of animals. The Jains take such matters a great deal more seriously than the Buddhists in part because, in the early texts, they do not believe that intention is a relevant factor in apportioning blame (Dundas 2003). Hence one can attract unwanted karma even by accidentally killing a creature. The Buddhist texts, on the other hand, communicate the view that intention is relevant and therefore unintentional killing is less morally blameworthy.

These Jain ethical practices are linked to more fundamental metaphysical views about the corrupting effects of evil thoughts and bad actions. Wrong action leads to the encumbering of the soul with karma thus preventing liberation from worldly rebirth. Only a pious lifestyle over many rebirths can remove the presence of this karma enabling liberation (Dundas 2003). This attitude toward spiritual purity influenced Jain food practices. Jain ascetics would become so concerned with ethical food consumption that it frequently led to fasting which in turn would sometimes lead to death (Basham 1951). The extremeness of such actions in part led to a division between the Svetambara and Digambara sects, the latter being the more conservative and the former being more pragmatic (Jaini 2007).

Ancient Buddhist texts, in particular the *Sutra* literature, state that the Buddha rejected a range of

different food consumption practices. For example, the Buddha disallowed the consumption of a number of different animals – elephants, lions, hyenas, monkeys, and others (Harvey 2000). These rules were implemented sometimes out of respect for the particular animals, such as the lion and the elephant, but also due to the notion that some of these creatures are unclean or not fit for human consumption, such as in the case of the monkey and hyena. The Buddha also opposed the consumption of human flesh (ibid). In many cases such as these, the evidence is that these rules were implemented for prudential reasons. In the *Vinaya*, an important, and ancient, Buddhist text of monastic legalism, we find the Buddha rejecting cannibalism seemingly out of concern that it would bring shame upon the monastic order (Stewart 2010, 2015). Nonetheless, the Buddha expressly rejects the ritual slaughter of animals and also condemns merchants who slaughter animals for economic reasons. Again, such bans did not lead to the mandatory adoption of vegetarianism, unlike in the case of Jainism.

The Buddha's overall attitude toward food was that of moderation (Harvey 2000; Stewart 2010, 2015). He believed that Buddhists should not overindulge in food and that food should be viewed as a fuel that supports the renunciate's life. In the *Vinaya* and in other ancient Buddhist texts, the Buddha limited monks to consuming no food after midday, and this has led to the customary practice whereby monks in South Asian Buddhist nations consume breakfast and a large meal at lunch but only take "medicines" and drinks in the afternoon. Monks were also completely banned from consuming, among other things, alcohol because it was viewed as an intoxicant that would inhibit the spiritual development of the religious aspirant. This stems in part from the wider Indian historical association between vows of chastity (*brahmacharya*) and food-limiting practices such as fasting (see ► [Fasting](#)). The common denominator among all these religions, whether orthodox or heterodox, is the need to control desire.

In line with the view that desires must be controlled for spiritual limitation, the Buddhist *Sutra* literature reports that the Buddha engaged in

stringent fasting practices that were associated during this period with orthodox Brahmanical renunciate practices. The Buddha found extreme fasting to be manifestly harmful so while he did believe that food should be strictly controlled, he did not adopt the idea that the total withholding of food was critical for spiritual advancement – unlike the Jains and the Ajivikas. This idea did, however, continue to be popular within the religious orthodoxy and elements of such practices can be found in all Indian religious traditions.

Buddhist debates surrounding the moral and spiritual justification for certain food consumption practices declined in importance as the religion of Buddhism ultimately expired in India. These debates were instead transplanted to surrounding nations such as Tibet, Sri Lanka, and Burma.

In the orthodox Vedic religions, the view that animal slaughter was an important aspect of the religion began to have less influence as fledgling heterodox religions such as Buddhism and Jainism started to develop. Some have argued that the *Dharmasastras*, especially the *Manusmriti* (a text that dates from the second to the third century BCE), maintains a contradictory view that can be interpreted as both endorsing and rejecting animal slaughter (Alsdorf 2010). This has led some scholars to posit that there was disagreement within the orthodox Brahmanical tradition over the importance of animal slaughter and that there is evidence that a trend toward animal non-violence was beginning to appear (Jha 2002; Alsdorf 2010). Nonetheless, animal slaughter in the orthodox Indian religions would never truly disappear, and even in India today, some Hindus continue to slaughter animals as part of their religious observances (Fuller 2004). Nonetheless, there is a strong Hindu movement that supports and promotes animal non-violence and vegetarianism in India, and so such practices are also, at times, discouraged (ibid).

An inevitable part of the promotion of the idea of non-violence was the rise of King Asoka (reigned 265–238 BCE) of the Maurya Dynasty. Asoka, seemingly inspired by his conversion to Buddhism, implemented a number of policies that banned or limited the hunting and killing of animals (Horner 1967). This would have

unavoidably led to the promotion of dietary practices such as vegetarianism and abstention from the consumption of meat. The main historic source for Asoka's rejection of animal slaughter is his rock edicts, some of which can still be accessed today (ibid). It has been argued, however, that Asoka's apparent pacifism finds its roots not necessarily in Buddhism, but instead in Jainism and orthodox Brahmanism (Alsdorf 2010). Still, the impact that Asoka has had on food practices in South Asian cultures cannot be disputed.

Meat Eating and Vegetarianism in Modern India

Modern Hindu food practices have not only been shaped by these ancient and premodern forces, but they have also been heavily influenced by more recent colonial forces. To begin with, early Western missionaries traveling to the subcontinent observed that the Hindus, especially in South India, took vegetarianism to be a crucial part of their religious observances (Stuart 2007).

While some missionaries respected Hindu food practices, many ridiculed them (ibid). This set up a competitive narrative between foreign (i.e., usually Western) interlopers on the one hand and indigenous Hindus on the other. From the perspective of some Hindus, European invaders were barbarians who had no respect for nonhuman life and, in particular, no respect for the sacred practices of the Hindus. They were especially appalled by the invader's tendency to slaughter cows and consume beef (ibid). Similar attitudes toward foreign invaders are present in Sri Lanka (Young 1995). During this period of occupation, there was great controversy in Europe as to whether converts to Christianity were permitted to continue their traditional practices which sometimes included vegetarianism (ibid).

This conflict between European invaders and local Hindus propagated a narrative between those interlopers who threatened indigenous customs and those who sought to protect them. This later influenced the Indian independence movement and, since then, the modern Hindutva (Hindu-only) movement. The Hindutva

movement, a Hindu nationalist movement in India, seeks to expel non-Hindu cultural practices, including food practices, from the country altogether.

In modern Hinduism, vegetarianism, and other food-limiting practices, is associated with caste purity (see ► [Hinduism and Food](#)). Typically, vegetarianism is nominally practiced by the Brahmin (priest) caste, which is the highest spiritual caste in the Hindu religion (Fuller 2004). Vegetarianism is part of a social hierarchy where certain food practices are understood to be conducted by a spiritual elite. Meat eating, on the other hand, is viewed as a baser practice and is affiliated with violence and martial excellence. Nonetheless, vegetarianism is not strictly associated with the Brahmin caste. Lower castes sometimes practice vegetarianism, often as a way to improve their social and spiritual standing (Mayer 1970). On the other hand, not all Brahmins practice vegetarianism and some Brahmins eat meat without any concern. For example, within the Kanya-Kubja community, some meats and fish are consumed (Fuller 2004). Furthermore, in modern India, religiously motivated vegetarianism is more commonly associated with South Indian Hindus and is more sporadically practiced in North India (ibid).

The practice of vegetarianism in India is also critically associated with concern over ritual pollution (Douglas 2002; Flood 2004). Ritual food management practices, especially in relation to the Hindu temple, involve strict pollution avoidance strategies, and sacred food items offered in temples are usually consumed by temple officials, not by the attending devotees (Fuller 1979). Food that has come into contact with low-caste individuals cannot typically be consumed by higher-caste individuals such as Brahmins. In the event of this sort of contamination, rigorous cleansing rituals are sometimes implemented (Flood 2004). These decontamination rituals include ritual bathing in sacred rivers such as the Ganges or the sipping of pure water. The ingestion of sacred water counteracts the ingestion of spiritual pollutants. The threat of intercaste pollution is considered so great that some never eat away from their homes in case they inadvertently come into contact with food

prepared by a member of the lower castes (Ghassem-Fachandi 2012).

Vegetarianism, as a spiritual activity, became particularly prominent during the colonial period. It was of particular importance in relation to the Indian independence movement. Dayananda Saraswati (1824–1883), the founder of the Hindu nationalist movement known as Arya Samaj (Noble Society), vigorously promoted cow protectionism as well as vegetarianism. Vegetarianism was, for him, a proper expression of the Hindu ethos (McLane 1977). Arya Samaj was a powerful historical force that helped install Hinduism as a national religion. The movement also had the effect of propagating the virtues of vegetarianism.

Mohandas Gandhi is another important figure among Hindus for propagating the role of food-limiting behaviors in pursuit of religious purity. Gandhi argued in favor of fasting as a method of controlling cravings and desires. For Gandhi, and other Hindus, controlling desire is a crucial pathway toward connecting with God (Van der Veer 1994; Tidrick 2013). Yet while Gandhi favored fasting, he was not the first to value fasting as a spiritual practice, and its roots originally lie in ancient Vedic sources and are adopted also in the heterodox tradition (Flood 2004).

Gandhi viewed vegetarianism as a basic practice of true Hinduism because it was an expression of the Hindu principle of non-violence. He also saw meat as a pollutant that needed to be expunged, not to mention the fact that he regarded vegetarianism as a prudential health necessity (Tidrick 2013). In line with his food-limiting practices, he also experimented with limiting other foods including salt and at one time even adopted a quasi-fruitarian diet that mainly involved him eating groundnuts and lemons (Gandhi 1993). Again, Gandhi connected food practices back to their Vedic origins (Ghassem-Fachandi 2012).

The practice of vegetarianism is increasingly popular as an expression of Hindu piety throughout India. In turn, animal sacrifice practices are becoming less popular as vegetarianism and concern over animal welfare continue to rise (Fuller 2004). Public restaurants in India sometimes go to considerable lengths to provide spaces that

accommodate both vegetarians and meat eaters (Ghassem-Fachandi 2012). Special secluded booths are made so that vegetarians and meat eaters can be segregated from one another (ibid).

Because of the issue of spiritual contamination, restaurants must sometimes employ complex food management systems to ensure that meat never comes into contact with vegetarian food (ibid). Despite such attempts to accommodate different dietary needs, the vegetarian movement is nonetheless associated with elements of the Hindu nationalist (Hindutva) movement. This movement is also concerned with cow protectionism and so the issue of vegetarianism in India is often concerned with ethnic and religious politics.

Aside from Hinduism, Sikhism – another indigenous religion to India – prescribes complex food consumption practices. Key figures in the history of Sikhism, such as Guru Amar Das (1479–1574 CE), refused to eat anything except rice and lentils, and this is sometimes construed by Sikhs as evidence that Sikhism promotes vegetarianism (Cole and Sambhi 1998). This has led some Sikhs to adopt a vegetarian diet and abstain from meat (ibid). Many Sikhs also refuse to consume beef because of their appreciation of the cow, but cow protectionism appears to be a pan-Indian practice (see ► [South Asia and Cow Protectionism](#)).

Still, there is disagreement about this within the Sikh tradition, and some Sikhs read passages of the *Guru Granth Sahib* (the central text of Sikhism) as rejecting universal vegetarianism. Other central historical figures of the Sikh religion, such as the prophet Guru Nanak (1469–1539 CE), appear to have eaten some types of meat such as lamb (ibid). Guru Gobind Singh (1675–1708 CE) also explicitly rejects the consumption of meat stemming from the *halal* method of animal slaughter. These injunctions coming from these important gurus have led some Sikhs to view this as an implicit endorsement of animal slaughter and therefore meat consumption, insofar that there are only restrictions on the method of slaughter (ibid). On the other hand, Sikh vegetarians interpret this as an independent criticism of Islam and view this as a statement about the need to avoid harm to animals

completely and not as a conditional allowance of meat consumption (ibid).

Another example of vegetarian practices in Sikhism is the existence of the *langar* or common kitchen. It is basic to the *langar* institution that the dishes be vegetarian (Dogra and Manuskhani 1995). Here, food is prepared by Sikhs as part of their religious commitment to community service. The food is then distributed to others in the community regardless of economic status or religious affiliation. This practice has been utilized by some Sikh leaders as a way to build bridges between communities (Cole and Sambhi 1998).

Islam is the chief religion of Pakistan and Bangladesh and is also widely practiced in India, Sri Lanka, and Burma. In accordance with normal Muslim food practices, it is considered a sin to consume meat that has not been prepared in a ritually pure manner known as *halal* (see ► [Islam and Food](#) and ► [Islam and Food and Agricultural Ethics](#)). This in part stems from a more basic concern over the consumption of blood, a material that is considered *haram*, or forbidden (Rippin 2011). Hence, Muslim animal slaughter practices are concerned with ensuring that food materials are free of blood. Muslims, as with other Abrahamic religions such as Judaism, also reject the consumption of pork and pig products. In the *Quran*, pig flesh is described as an “abomination” (ibid). The general question of why pigs are so maligned has been vigorously debated by scholars for some time. One explanation for why pigs are rejected is out of a concern for hygiene, though Mary Douglas has argued that it is because pigs do not fit properly into ancient animal classification schemas (Douglas 2002).

Muslims also ritually slaughter animals for the Bakra Eid festival. The remains of these animals are typically distributed among the poor. Yet this festival, which often involves the slaughter of cows, has sometimes led to conflict between Muslims and Hindus (McLane 1977). Therefore, there are animal sacrifice practices within the Islamic tradition, just as there are within the Hindu tradition. Controversy over such matters has led to some interethnic and interreligious conflict in a number of South Asian nations including India and Sri Lanka.

Meat Eating and Vegetarianism in Buddhist Nations

Vegetarianism has historically been a complicated issue within South Asian Buddhist communities (► [Buddhist Perspectives on Food and Agricultural Ethics](#)). In India and Nepal, Tibetan diaspora communities typically consume meat without problem, though it appears that some monks do practice vegetarianism (Gurumurthy 1980). There is a tradition within Tibetan Buddhism for vegetarianism, and some influential monks have adopted and endorsed vegetarianism as a proper expression of the Buddhist principle of non-violence (Barstow 2013). It is clear that such figures will have some influence on Tibetan diaspora communities in India and Nepal.

The historical origins of vegetarianism in South Asian Buddhist communities are equally complicated. In Sri Lanka, vegetarianism appears to predate European colonization. There are reports in indigenous Sinhalese chronologies that indicate a respect for vegetarianism and a rejection of specific meat consumption practices, in particular beef and fish (Stewart 2015). Later European settlers and explorers also report that Sinhalese Buddhists regarded vegetarianism as a dietary ideal, even if many did not practice it. For example, Robert Knox, an explorer who was marooned in Sri Lanka during the Dutch occupation, observed that pious Buddhists practiced vegetarianism. He also noted that beef eating was so thoroughly rejected that European colonists were derisively referred to as “beef-eating slaves” (ibid). Even older reports from Sinhalese records indicate a general disbelief of colonial dietary practices. In particular, the Catholic Portuguese’s consumption of meat and wine was derided by Buddhists, and reimaginations of the Biblical tale of Christ were produced to ridicule Catholic beliefs and practices. These stories depict Christ as a demonic figure who is addicted to alcohol and meat (Young 1995).

Within Sinhala Buddhist communities, some of these concerns stem as much from Hindu cultural influence as it does from their Buddhist beliefs. For example, the rejection of beef eating appears to have its roots in imported views about the need to protect cows (ibid). These beliefs of

course lead to Muslim-Buddhist conflict as in India. Objections are similarly raised against the killing of fish in Sri Lanka, and this has led to intercaste and interreligious conflict since the fisher people in Sri Lanka are predominately Christian and of the Karava caste (ibid). The intersection between caste, ethnicity, and religion therefore plays a strong role in dietary practices in Sri Lanka.

Views about meat, however, are complicated by other spiritual and religious beliefs. For example, it is clear – as in the case of Hindu India – that meat has a particular power concerned with violence and martial ability. This association means that meat is typically affiliated with demonic entities and therefore plays a crucial role in exorcism rituals (Kapferer 1991; Mayer 1970). Likewise, some key deities, such as Kataragama, are sometimes given flesh as a sacrificial offering (Gombrich and Obeyesekere 1988). Kataragama is a war god and a deity worshipped by Sinhala Buddhists and Hindu Tamil Sri Lankans alike and is of considerable cultural importance (ibid). Nonetheless, the need to offer flesh to these violent deities is in tension with a recognition that such gods should be encouraged to act in a morally upright manner. Hence, fruit platters are the main offering that Kataragama receives, even though many accept that he prefers meat (ibid; Stewart 2015). After the offering is complete, and the platter of fruit has been blessed, the fruit is then consumed by the devotees or fed to nearby animals (Stewart 2015).

There is some recognition that good deities should be supplied with vegetarian offerings and violent and/or demonic deities prefer flesh (Obeyesekere 1963). Buddha images at temples are commonly offered vegetarian food, and at the most holy Buddhist site in Sri Lanka, the Sri Dalada Maligawa (Temple of the Holy Tooth), only vegetarian food is allowed to be offered to the Buddha relic (ibid). On holy days (*poya*), many Buddhists abstain from meat and intoxicants, such as alcohol and tobacco, entirely (Gombrich 2009; Stewart 2015). Some Buddhist restaurants will only serve vegetarian food on holy days (Stewart 2015).

All of this indicates that vegetarianism has positive religious associations in Sri Lanka,

while meat is negatively affiliated. Still, while vegetarianism is respected among pious Buddhist laypeople, it is not necessarily commonly practiced (ibid). While some Buddhists are wary about the killing of fish, fish is a mainstay of the Sinhala Buddhist diet. On the other hand, monks are especially critical of ethical vegetarianism because they interpret the Buddha's original message to be one of indifference toward vegetarianism (ibid). This relates back to ancient debates over the moral need for vegetarianism and some Buddhists continue to see it as an unnecessary form of asceticism.

The cause of vegetarian culture in Buddhist Sri Lanka is the result of a range of factors by a range of factors, not all of which are religious. From the perspective of religious ethics, some Buddhists insist that it is the proper expression of the first Buddhist precept of non-violence. A few pro-vegetarian Buddhists even cite the Buddha as a moral authority on this, and many arguments over the virtues of vegetarianism relate to arguments about the Buddha's final meal (Harvey 2000; Stewart 2015). Some argue that the Buddha's last meal was a vegetarian one thus implying that the Buddha was vegetarian. Such claims have been rejected by Western and non-Western scholars alike (Harvey 2000; Stewart 2015), though even modern Sri Lankan Buddhists continue to maintain such views (Stewart 2015).

In Burma, as in Sri Lanka, there is a culture for Buddhist vegetarianism. Buddhists there sometimes view vegetarianism as morally justified given the Buddha's view on non-violence. In particular, the monk Mahasi Sayadaw (1904–1982), who was a monk of great significance in Burma, recommended vegetarianism as a way to guarantee that food has not been associated with the killing of animals – which would be a transgression of the first precept and would result in the violation of a monk's religious oaths (Harvey 2000). Another influential monk, Thamanya Sayadaw (1910–2003), also argued for vegetarianism, but rather than arguing for this diet as a prudent way to accidentally avoid violating one's monastic vows, Thamanya saw vegetarianism as a way to uphold the Buddhist principle of *metta* or loving-kindness (Houtman 1999).

These more modern Burmese monks find their roots in other Burmese figures, in particular Ledi Sayadaw – one of the most important Buddhist monks in Burmese history. He recommended and adopted a strict vegetarian diet (Braun 2013). Sayadaw was also a major force of religious reformation in Burma, was involved with the Burmese independence movement, and was also an integral force in the development of Burmese nationalism. His interest in vegetarianism extended to other related areas including cow protectionism. Even in contemporary Burma, virtuoso monks with a great deal of social and religious influence continue to promote vegetarianism. U Thuzana, a pupil of U Thamanya, for example, is one such individual who promotes vegetarianism and non-violence (Gravers 2005). In many cases, the promotion of vegetarianism in Burma has been historically associated with a pious Buddhist lifestyle that should be practiced in anticipation for the arrival of the next Buddha, Maitreya Buddha (Hayami 2011).

Vegetarianism in Burmese culture is also associated with esoteric spiritual practices. Those who practice non-Buddhist eschatology – in Burma essentially a type of alchemical magic – adopt what would be considered nonconventional practices including vegetarianism. These alchemists, called *weikza*, shun ordinary human society including meat consumption, as it is viewed as a dirty, unclean, and spiritually harmful custom (Spiro 1982). This is another example, as in the case of Sri Lanka, where food practices such as vegetarianism are not just restricted to the majority religion but are also influenced by other customs and practices that have been adopted through social accretion from surrounding countries. Also, as in the case of Sri Lanka and India, vegetarianism in Burma has associations with the development of spiritual improvement.

Food and Traditional Medicine in South Asia

The treatment of food in terms of traditional Indian medicine is less concerned with moral purity, as is the case in the above discussion of

food in its religious domain, and is more concerned with the practical implications of food consumption practices (see ► [Medicalization of Eating and Feeding](#)). In relation to food practices, traditional medicine in South Asia is concerned mainly with the prudential issue of improving one's health.

In India, traditional medicine is mainly associated with the Ayurveda (“the science of living (to a ripe age)”) (Basham 1976), a tradition that has its roots in practices dating back from 1000 BCE (Warrier 2016). Ayurveda has also absorbed other traditions such as Unani, a traditional medicine of Perso-Arabic and Greek origin that was received in India from around 11CE (ibid).

Ayurvedic medicine has been transplanted from India to neighboring countries, especially Sri Lanka and Nepal. In Sri Lanka, traditional medicine – much of which comes from the Ayurvedic tradition – is important in local health practices. It is considered a legitimate option for treating ailments and is sometimes in competition with Western medical treatments. Nonetheless, it has been argued that the encounter between Ayurvedic medicine and the West is such that Ayurveda no longer has a distinctive identity and has been highly biomedicalized (ibid). Traditional practitioners of indigenous medicines were forced to adapt during the colonial period as European colonists looked upon Ayurvedic and traditional medicine with disdain, regarding it as a backward and primitive custom (ibid).

The basic principles of traditional medicine in South Asia involve, among other therapies (including meditation, purgation etc), food control practices in conjunction with the ingestion of medicines specially prepared by traditional doctors (Engler 2003). These medicines are usually composed of animal and plant materials that have been prepared in a particular manner prescribed by Ayurvedic texts that are often thousands of years old.

Ayurvedic medicine is based around a humor (*dosha*) theory of health. The three humors dealt within Ayurveda are wind (*vayu*), bile (*pitta*), and phlegm (*kapha*) (Warrier 2016). Maintaining the correct balance of these humors is the primary goal of Ayurvedic practice and

diet is critical in this. Different types of food can excite one or more humors and result in an imbalance that can lead to mood changes or ill-health. Some foods can result in the excessive production of heat, others lead to excessive cooling, others promote the production of phlegm, others inhibit phlegm production, and so on. On the other hand, the *satvic* ayurvedic theory emphasizes the importance of controlling the amount of heavy (*tamasic*) versus light foods that are consumed. Again, balancing these foods is crucial. Because onions are “heavy,” excessive onion eating can lead to ill-health. On the other hand, sometimes the excessive consumption of these foods is necessary to overcome other more serious illnesses. For example, there is a (likely somewhat fictionalized) tale of King Asoka falling very ill with a gut parasite. It was determined that the parasite was weakened by onions, and so King Asoka was made to eat an excessive number of onions in order to be rid of the parasite (Basham 1976). A basic principle of Ayurveda is that, when food is ingested, it is then subject to “cooking” in the body (Engler 2003). The type of food and the quantity of that food are variables that can lead to humoral imbalance and, consequently, illness.

Therefore, in many Indic cultures, paying close attention to your diet is critical in maintaining good health, and there are complex views about what constitutes an appropriate food to consume. Overall, the goal of Ayurvedic medicine is to prolong life (ibid).

It is interesting to note that the traditional student doctor was originally supposed to be an exemplar of good health and his motives for taking up the profession were expected to be pure. It even seems that, originally, the student doctor was meant to obey a good diet by being a vegetarian (ibid). In some instances, authorized doctors were required to sip samples of a patient’s urine as part of their diagnostic testing. Despite the fact that such practices would be potentially polluting, there is no obvious evidence that a doctor was to undergo purification rites, and therefore it seems that religious taboos were relaxed for medical professionals (ibid).

The ancient medical texts upon which modern Ayurvedic medicine is based are also concerned with dietary habits (Basham 1976). Some of these ancient texts quite explicitly provide instructions to avoid food poisoning (ibid). In fact, Ayurvedic texts such as the *Charaka Samhita* and the *Sushruta Samhita* recommend the use of special rituals in order to cleanse food of contaminants (Engler 2003). Ancient Ayurvedic pharmaceutical practices are of particular note here, as they recommended the consumption of various herbs and other foods that, when consumed, affected the humors in a desired way thus bringing balance back to the body. It has been suggested by some scholars that these ancient Ayurvedic texts appear to require that, in the preparation of medical compounds, meat and meat products be used (ibid). The requirement that a student doctor should adopt vegetarianism does not imply that vegetarianism was always considered medically beneficial. At least sometimes meat was needed to improve one’s health.

Apart from medical benefit, some plants were consumed for spiritual advantage. In particular, the soma plant was used in the composition of a beverage that was drunk by the Brahmin priest caste to induce hallucinations and help facilitate spiritual insight (Flood 2004). The consumption of certain plants therefore entailed particular spiritual advantages though the use of such materials went out of favor in part because the *soma* plant seems to have become extinct (ibid). In non-esoteric forms of modern Hinduism, intoxicants are typically discarded because they are construed as pollutants. In esoteric Tantra, however, intoxicants – such as alcohol – are sometimes consumed for spiritual edification (Flood 2004; Fuller 2004).

Other unique materials used in Ayurveda include cow’s milk, which is considered especially potent at curing disease and illness (Engler 2003). In Sri Lanka, cow’s milk is frequently viewed as having a curative property and is regarded as having special health benefits (Stewart 2015). The special curative properties of dairy products are also a feature of the Hindu religion as well (Fowler 1997).

In modern India, Ayurveda and ancillary traditional medicines continue to be popular, though Western medicine is still the most popular form of medical treatment (Islam 2009). Ayurveda is often sought after when Western treatments fail or are considered inadequate in controlling symptoms (ibid).

In Sri Lanka, traditional medicine – which is also largely Ayurvedic in nature – is very popular regardless of ethnic or religious affiliation. Again, traditional medicine can have an impact on shaping one's diet and general attitude toward food. In Sri Lanka, the same basic principles of Ayurveda already discussed hold, and sometimes Sri Lankan Ayurvedic doctors travel to India for their education. Sri Lanka, in fact, has a proud history of medical innovations and there is evidence of a number of ancient hospitals. These ancient hospitals also illustrate some of the novel ways that food was used as a way of treating patients. In particular, the use of immersion baths was prescribed as an alternative mechanism for ingesting medicines. Using immersion therapy, medicines – composed often of milk, ghee, oils, and vinegar (again, nominally also ordinary foods) – were absorbed through the skin rather than orally (Mueller-Dietz 1996).

In modern Sri Lanka, efforts are made to control undue “heating” and “cooling” (brought on by an improper diet, among other things) in a variety of ways. In particular efforts are made to appease the goddess Pattini, a deity associated with well-being and health (Obeyesekere 1976). She is also thought to be sometimes responsible for excessive “heating” because she is construed as a deity who is irascible and easily angered (ibid). When rituals to please Pattini are complete, Sri Lankans dine on special foods such as milk rice (*kiribath*), turmeric water, and leaves from the neem tree. In general, when illness cannot be explained by bad karma or other forces, sometimes traditional doctors will determine that illness is a result of a poor diet that brings on excessive “heating.” As Obeyesekere explains, sometimes correcting that diet proves impossible, in which case special “cooling” medicines are provided as a way to minimize the effects of the diet (ibid).

Common and exotic animal and plant materials are sometimes used in Ayurvedic preparations. One study showed that even creatures such as elephants and tigers are said to be used in the composition of some remedies (Stewart 2015). This can prove to be a problem in cases where the slaughter of such animals is restricted or banned. In Sri Lanka, the killing of elephants, for example, is strictly controlled and in many instances is illegal. Nonetheless, dedicated Ayurvedic doctors feel compelled to source the materials from somewhere if it is necessary to alleviate a patient's illness (ibid). Some Sri Lankan traditional doctors do not consider animal welfare issues a priority in their medical practice, while others believe that true Ayurvedic medicine should be strictly vegetarian (ibid).

In Pakistan, traditional medicine is governed primarily by the Unani medical tradition, a Perso-Arabic origin, though this form of medicine was originally invented in ancient Greece (Sheehan and Hussain 2002). Ayurveda still plays a role in traditional medicine in Pakistan, however (ibid). Regarding food, similar principles apply as in Ayurveda (though, over time, Ayurveda has been significantly influenced by the Unani tradition). For example, as in Ayurveda, food is broken down and “cooked” in the stomach. Unani is also based around a humoral theory. Again, as in Ayurveda, Unani doctors may recommend a treatment that involved some amount of food restriction (ibid). Different foods may also be utilized in order to control or remedy illness. Animal parts are sometimes ingested to cure corresponding injury in the human patient – e.g., kidney may be recommended for consumption in order to rectify kidney disease (ibid). In Unani, the diagnosis of illness is made in part through monitoring food consumption. In particular, doctors sometimes examine a patient's feces in order to better understand the patient's food consumption patterns. In these matters, Unani is again similar to Ayurveda.

Conclusion

Food ethics in South Asia is often dominated by debate over the religious and spiritual importance

of food consumption. These debates are frequently concerned with the questions about the moral viability of meat consumption. Meat is sometimes construed as perfectly morally acceptable, while at other times, it is seen as a spiritual pollutant. In other instances, meat consumption is seen as a violation of the principle of non-violence, a view that is held among almost all Indian religions. This concern over animal welfare is especially obvious in the case of the cow. Apart from these religious considerations, prudence also plays a role in food consumption practices. The intersection of food ethics with prudence is most obvious in the case of indigenous medical practices such as the Ayurveda or Unani medical traditions. Finally, there are more basic ethical and moral questions about food production that are concerned with the agricultural sector where labor exploitation continues to be a problem.

Introduction

Ancient petroglyphs around the world testify to hunting being one of the oldest food procuring practices among humans. Tracking, trapping and killing wildlife have shown continuity as cultural practices from the earliest nomadic hunters and gathers, over agricultural settlements, and the domestication of wild animals, to the industrialized societies of modern times (Geist 2010).

Although hunting no longer constitutes an indispensable practice for our survival of human beings in general, it remains a widespread phenomenon in most parts of the world. Indeed, while ratio of hunters to nonhunters has declined, some parts of the world have seen hunting increases in popularity, attracting new hunters across several demographic axes, including urban residents and women (Hansen et al. 2012).

The development constitutes an ostensive paradox. Since foods are conveniently available to us in the nearest supermarket, one might wonder why some people still find it worth the effort to go hunting. In Roman culture, it was a common refrain that hunting was a waste of time, largely to be conducted out of necessity by shepherds defending their flocks or by professional trappers (Geist 2010). With even less need to hunt today, the perseverance and popularity of hunting is anachronistic (Cahoone 2009). Its anachronism as a food-procuring practice is accentuated by the fact that hunting embodies an inherent tension between its approximation of preagrarian atavistic rituals and its contemporary praxis.

As contemporary hunting detaches from subsistence-grounded food consumption to embrace more sport elements into its remit, ethical codes around killing and harvesting change. The gradual transition of hunting into a leisure or sport has been both facilitated and, one might argue, simultaneously circumscribed by continuous technological development enabling more efficient harvesting. When the technological revolution presented hunters with advantages that greatly increased harvest rates, such long range and high precision weapons, and vehicles enabling practices across previously untraversable terrains (Gutiérrez et al. 1979; Pauley 2003), the balance between prey and hunters dramatically shifted. As a corollary of this, ethics of restraint were codified to conserve wildlife stocks for future use. This codification took broadly two pathways: formal laws enacted by authorities to limit excessive outtakes of game, i.e., regulation from above, and informal norms and customs pertaining to fair chase. Hunting ethics were thus subject to two parallel domains of rules: a legal and a moral-cultural.

Through most of the history, these two domains have operated in a complementary fashion as the norms that undergirded hunting were also shared by majority society. Most people had some embodied or familial connection to hunting. With time, however, society's formal institutions and the scrutiny of an increasingly skeptical public opinion have enacted prohibitions around customary hunting practices and game. That the freedoms characteristic of hunting have increasingly been restricted, by everyone from feudal lords to colonial powers to successive ways of environmental regulation and animal rights, is now a common concern among hunting proponents. Hunting has often responded to this outside threat by re-asserting its autonomy and tradition, whereby outside regulation for how to harvest and kill is taken as encroachment in its domain (Thompson 1975; MacDonald 2005).

We use the following space to illuminate the most crucial political and social issues emerging from the place of hunting in modern society. We review the drivers of modern hunting as a food procuring and emancipatory practice in industrialized society, the ethics of hunting, and examine how hunting evolves in a dialectic with modern society, sometimes contradicting and sometimes affirming values or meeting new needs that emerge from the comforts of city life. Using concrete examples, we illustrate how hunting is practiced in an ambivalent mode that transcends itself and reflects some the social and political ambivalences of modern society.

Drivers of "Modern" Hunters

The number of card-carrying hunters varies internationally depending on available statistics, methods of calculations, hunting traditions, national legislation, and accessibility to game and firearms. Using Europe as an example, the registered hunting percentage of the population varies from less than 1% to more than 5%. According to FACE, *The European Federation of Associations for Hunting & Conservation*, approximately 11 million hunters are registered across 35 countries in Europe, not including a

number of Eastern European countries, such as Russia. In the United States, hunters total approximately 16 million, broadly equivalent to 6% of the population (US Fish and Wildlife Service 2011). The relative exclusivity of hunting can sometimes be traced to historical accessibility of wildlife across socio-economic classes in society. Hence, the grammar of contemporary hunting is often a legacy of historical class antagonisms pertaining to property rights. In England and in Germany, for example, hunting is associated with aristocracy, whereas in Finland, Norway, and Sweden there is a stronger "killing-for-the-table" tradition that today implicates the working class or transcends class altogether. In most countries, however, hunting is an amalgam of multiple class cultures where at best distinct forms of hunting are associated with different classes.

Wild game meat enjoys a high status and is currently shown to promote the nonhunting public's acceptance of hunting (Ljung et al. 2012). Game meat takes on different statuses depending primarily on three factors. First, the amount of edible meat per unit killed confers higher status to big game. Second, in some indigenous cultures, the consumption of certain meat is seen associate the consumer with the qualities of that animal; that is, if one eats bear one is said to channel the bravery and strength of the bear, or else subsume the masculinity associated with wild game meat (Hell 1996). Third, the status of game meat is often correlated with the difficulty of hunting the animal and its relative scarcity, promoting the appeal of exotic animals.

Why do people today choose to hunt to the extent that they do? The answer may be approached from three different directions. The first approach is a genetic one, based on the premise that hunting is an instinctual outlet (Causey 1989). The second sociological approach predicates on the assumption that hunting now serves as a response of the individual to social needs that emerge within contemporary society. The third approach is based on what the hunters themselves argue to be the reasons why they hunt, which include both utilitarian and esoteric motives, such as the excitement, the challenge, the trophy, the embodied connection with nature, the

relaxation, working with hunting dogs and social value of being together (Good 1997). Analyses of motives are often based on a combination of the two latter approaches.

Studies also show correlations between demographic variables and distribution of hunter motives and preferences. One dominant empirical finding across diverse contexts has been that hunters graduate through different phases where motives and ways of relating to the quarry correspond broadly to life stages (Kellert 1978; Kaltenborn et al. 2013). On these studies, young hunters typically emphasize excitement; hunters between ages 30 and 40 emphasize the relaxation of the experience, hunters aged 50–60 emphasize the trophy aspect, while elderly hunters value the social dimension to hunting. Another empirical finding has been to correlate hunting preferences with the hunter's demographic background, whereby urban residence and the lack of familial ties with hunting correspond to a stronger preference toward big game hunting (Hansen et al. 2012).

Possible reasons for such correlations may involve the fact that whereas small game hunting typically requires transferred knowledge and experience, big game hunting is an accessible first-port to new hunters (Decker et al. 1984). Further, such hunters are increasingly recruited among urban residents who start out with little or no personal hunting experience, and more and more hunters appear to be introduced to hunting scholastically. Hence, the profile of the contemporary hunter, including his or her knowledge, ethic, and preferred type of game, might not be the same as that of the “classical” hunter a few decades back.

That is not to say the contemporary urban hunter is out-of-touch with hunting ethics. Indeed, the return to hunting in postmodernity may be taken as a counter-reaction to the alienation between man and nature in our society that can bridge the gap between our food procurement and instant needs. Our urban lifestyle is now critiqued by proponents of sustainability for detaching from standards of self-sufficiency. Some scholars have characterized this as contemporary society having become a Risk Society (Beck 1992), to which the return to hunting can be seen as a conscious or

unwitting response by urban populations to reconnect with nature. This much is reflected in the discourse of hunting associations, which promote hunting as a modern virtue that cultivates competences lost in modern society (Luke 1997). On this view, hunting has been presented as a neo-primitivist approximation of our heritage and as a cure for the “disease” of agricultural society, delivering us sanity through a mended connectivity with nature and wildlife (Swan 1995). Indeed, hunting defenders often pit the practice against modern agricultural production, which is taken as a greater threat to animal welfare, killing “...more animal than deer hunting per unit of nutrition” (Cahoone 2009, p. 81).

It might be asked whether or not the present situation demonstrates that hunting is successfully bridging the gap between man and nature created by our modern urban lifestyle. While on the level of the individual hunter self-accomplishment may be realized through a hunting lifestyle, there are also ways in which contemporary hunting has moved further from its pre-agrarian roots. The influx of new demographics and values, for one, has meant hunting has been infused with a commodity dimension: trophy and canned hunting have become stronger trends, where both the materials harvested and the experience itself are commodified for the hunting client. Given the nonhunting public's generally low tolerance for such hunting, evidenced not least recently in the global outcry of Cecil the Lion, commodification brought about from urban hunters also undermines the status of hunting in modern society by severing ties with its basis in killing-for-the-table. As a result of this, hunting associations today typically devote extensive resources to cleaning up contaminating events and discourses within hunting to project a more virtuous representation to the outside. Not surprisingly, then, role of *hunting ethics* as regards the wildlife and harvest has received renewed importance.

The Need for an Informal Ethical Code

Many hunting communities globally have retained ancient codes of conduct for their

hunting, including ethical standards around killing, harvesting, honoring kills, and sanctioning peers that violate such norms (Krange and Skogen 2007). Even before the influx of urban hunters and technology, hunters may be said to have worked with proto-ethics of restraints, in the form of enacting fairness principles and rituals around the taking of animal lives. As Hell (1996) argues, no hunting historically has ever been "...free from constraints and no spilling of blood is ever regarded as a banal act" (p. 209). Many totem species, for example, were or remain considered taboo in traditional subsistence cultures; many modes, seasons, or dispositions of killing have been characterized as dishonorable, and failure to make use of the material resources harvested may still be sanctioned as unethical and wasteful. Fairness principles vary globally. In many Native American tribes, hunters have operated with the refrain that nature "willed" sacrifices to man, provided he undertake the proper rituals to display his gratefulness (Hettinger 1994). This could involve explaining to the animal why it needs to be sacrificed, asking of its forgiveness and mourning its death, in addition to the complete usage of every part of it (Gunn 2001).

Excessive or wasteful outtakes, on this view, are violations of this exchange with nature and were linked to nature sanctioning man with natural disaster, poor harvest, and decreasing stocks of wildlife in the future. The frontier mentality of settling Europeans in North America imposed a decidedly less restrictive ethic as far as hunting was concerned (Kerasote 1994). At the same time, norms were also cultivated on sportsmanship conduct that continues to bear on hunting ethics today. These norms were predominantly associated with the emergence of field sports in Europe and the stratification of the hunting institution into lower class subsistence hunters and gentlemanly sportsmen (Nurse 2013). Fair chase became the guiding principle on which this stratification and, later also, neo-colonialism, turned in hunting. This is still reflected globally, where visiting sportsmen are held as more ethical hunters than indigenous people, who may be characterized as slob poachers or wasteful natives (Wall and McClanahan 2015).

Hunters' ethic of fair chase necessarily raises the question: "fairness to whom?" Scholars note that the origin of fair chase may have been less about protecting the integrity of wildlife, and more as an anthropocentric ethos of civility for paying dues to the institution of hunting (List 1998; Van de Pitte 2003). Bag limits are followed, first and foremost, to that others can enjoy the activity. Codes are often ostensibly about not offending others' sensibilities by inappropriate displays of the quarry. The anthropocentric character to hunting ethics may be partly attributed to the intensely social enterprise that characterizes hunting, one that has required cooperation and reciprocity to offset the hit-and-miss nature of hunting as a food procurement tactic (Gaus 2015). Scholars however observe that the extant fair chase ethic may provide a cover for a "ruthless efficiency" pursued behind many trophy hunting clubs like Boone and Crocket and Pope and Young (List 1998; Peterson 2000). But the ethic has also been infused with sustainability thinking, extending from proximate peers to the disembodied future generations or, even, to respect the integrity of sentient animals or the biotic community. Leopold's *Land Ethic* provides a seminal articulation of the latter. As part of nature reconciliation, hunters appear to become more pious about the value of nature as urbanization proceeds (Samuel 1999; Scruton 2000) and display ambivalence toward killing as well as an often profound respect for wildlife (Luke 1997).

The Place of Hunters in Contemporary Society

Today, the institution of hunting negotiates its social legitimacy by highlighting the multi-functional basis for hunting in modern society. That is, hunting can be legitimated both utilitarian grounds for the common good and more esoteric ones of self-actualization. Not only does it constitute therapeutic wildlife management by sustainably regulating wildlife stocks, but it also provides heurism, the promotion of virtues like self-reliance and prudence, and a sustainable food procurement (Loflin 1984; Curnutt 1996;

Shepherd 1996; Paulson 2012; Kover 2014). Hunting proponents present the hunting of animals as the more natural, local, and honest alternative to modern food production with its factory farming and global importing scheme (Luke 1997). It means the huntable quail, to name an example, has a higher status of meat than does chicken when it comes to fine dining. Cahoon (2009) formulates this as a form of responsible carnivory which, unlike capitalist-driven agricultural enterprise, reconciles workers with the product of their labor in a very direct sense. Industrialized slaughtering, by contrast, requires a suppression of empathy for animal suffering by taking place in a compartmentalized, desensitized manner (Berreville 2014).

The extent to which hunting provides an honest and direct food consumption in the ways characterized above, however, is contested by ecofeminists (Kover 2014). They observe the hunter actually goes to great lengths to mask the connection to killing what were once live animals by masking their identities even on the level of language: as deer/venison and calf/veal (Adams 1991). While hunting may thus qualify as part of a growing locavore discourse (Cope 2014), its logic is held to reproduce the same separation of people from the sources of their food of which hunters routinely accuse capitalist food production (Kheel 1995).

As to the more utilitarian argument of wildlife management, the value of stewarding wildlife populations through hunting often turns on the notion that it is supposedly less painful for an animal to die from a swift gunshot than to perish from disease, starvation, or interspecies predation in the wild (Loftin 1984; Cahoon 2009) – to say nothing of their fate in factory farms. On this view, hunters have been said to seek legitimacy by presenting themselves as “Florence Nightingales with rifles” (Kerasote 1994), as stewards caring enough to intervene in nature’s grisly drama (Samuel 1999). Their ethical status also derives from trophic responsibility from occupying the role of apex predator overseeing cascade effects in ecosystems and regulating them through feedback when required. It is significant that in some parts of the world, the word for wildlife

management as undertaken by hunters is equivalent to “wildlife *care*,” imparting a feminist care undertone to an otherwise masculine institution that is predicated on a separatist and controlling logic (Curtin 1991).

To this end, a number of developments threaten the legitimacy of hunting by presenting challenges to its guiding principle of fair chase and undermining its fundamental justification of self-reliance, connectivity to nature and responsible wildlife stewardship. While essential for its continued survival, the influx of urban outsiders into the community of hunters also involves changes to the internal logic of hunting. The sport and commercial dimensions to hunting arguably present the biggest obstacles to its survival, because they violate received notions of fairness as anchored in a subsistence basis. Poaching natural resources like rhino horns and ivory is declared immoral, and the killing for sport in game ranches (“canned hunting”) has been characterized as “*The single most alarming trend in hunting today*” (Loftin 1984, p. 249). Collectively, these developments reflect the commodification of hunting in contemporary society, turning hunters into clients, wildlife managers into brokers, and wild animals into domesticated trophies.

The preferred internal line of defense toward this has been to de-label these people as hunters and the enterprises as hunts. Rather, they are slaughterhouses (Pauley 2003), brothels, or amusement parks in which hunters are encouraged to hunt less with their “boots, brains, and hearts” than with their gadgetry and wallets (Peterson 2000). The aversion to commodification of hunting has been explained by the symbolic contamination that takes place when money, as opposed to goods, services, and relationships, becomes the transactional currency at hunts (Gezelius 2002). Money, greed, and excess are seen to lead to a loss of social control in the hunting context, enabling anonymous transactions between strangers where before cultural custom and norms of fair chase informed the code of conduct by hunters. Insofar as canned hunts and urban hunters are taken to stretch hunting ethics, they do so in particular following the characterization of hunting as a game rather than

subsistence. Additionally, failing to harvest the resources of a killed animal contaminates that act by severing the connection to subsistence and food.

Conclusion

To conclude from the above, hunting is subject to a dense undergrowth of informal ethical codes around killing, one that has grown in complexity with environmental legislation and pressure from animal rights activism. Yet it is striking how hunting has retained relative continuity in the face of societal change, at heart being about embodied food procurement in nature. We suggested multiple forces continue to challenge this: commoditization and sport hunting being the principal threats. Hunting must thereby strive to survive in contemporary society by maintaining a delicate balance between “killing for the table” and “playing the game.”

Stoicism and Food

Introduction

The ancient Stoics believed that virtue is the only true good and as such both necessary and sufficient for happiness. Accordingly, they classified food as among the things that are neither good nor bad but indifferent. These indifferents included health, illness, wealth, poverty, good and bad reputation, life, death, pleasure, and pain. How one deals with having or lacking these things reflects one's virtue or vice and thus determines one's happiness or misery. So, while the Stoics held that food in itself contributes nothing to a person's happiness, how one obtains, prepares, and serves it, and both what and how one eats, all reveal a person's character as good or bad. Thus, understanding the purpose of food, the necessity of frugality, and the virtue of temperance are all important in Stoicism.

Stoicism was the most important and influential school of Hellenistic philosophy. It became the foremost philosophy among the educated elite in Greece and Rome. Stoicism exerted a profound influence on Christianity and a pervasive impact on the history of western philosophy and culture through the Renaissance, the Enlightenment, and up to modern times. The

history of the ancient Stoa is typically divided into the early (Zeno through Antipater), middle (Panaetius and Posidonius), and late (Roman) periods. Since the vast bulk of the surviving texts about Stoicism come from the late period, the Roman Stoics' views about food will dominate here.

The Early Stoics

Around 301 BCE, after being stranded by shipwreck, Zeno of Citium, a merchant from the isle of Cyprus, began philosophizing in the Painted Colonnade (*Stoa*) of the great piazza of ancient Athens. The members of the school he founded were called Stoics. To help illustrate the art of living described by this philosophy, the early Stoics developed a model of the perfect human being called the wise man or sage. The sage represented a theoretical ideal which aspiring Stoics could strive to approach. One of the few surviving sources on the early Stoics, Diogenes Laertius (D.L.), reports that the Stoics attributed many perfections to the sage. They said the sage will never form mere opinions, will never assent to anything false, is infallible, does all things well, and does no harm to others or to himself. D.L. adds that the Stoics say that the sage "will even turn cannibal under stress of circumstances" (Laertius 1925, vii. 121). Such circumstances could perhaps have been during a siege, for example, when starvation would be the only alternative to anthropophagy. The idea seems to be that the sage would infallibly recognize those (rare) circumstances in which eating human flesh would be wise. Thus, the early Stoics evidently believed that cannibalism is not absolutely prohibited for the wise.

Chrysippus, the third head of the Stoa, supposedly reasoned that since the body is of as little importance to us as our nails or hair, it requires minimal attention, and so we should use the simplest method to bury our parents when they die. If human flesh is useful as food, he argued, then people should make use of it. Our amputated limbs should not be buried or discarded but rather eaten so that they will

give being to our other parts (Avramescu 2003). If a motive implicit in Chrysippus' view of anthropophagy is to conserve edible food and avoid waste, then he shares the value of frugality with the Roman Stoics.

The Stoics of the Roman Empire

Food and banquets were highly significant in Roman culture, religion, literature, and law. Roman sumptuary laws regulated and reinforced social hierarchies and moral norms by restricting food, clothing, and luxury expenditures, often according to a person's social rank. Accordingly, the Roman Stoics praised frugality, simplicity, self-control, and strategic abstinence, while condemning indulgence and worries about either eating or starving.

Lucius Annaeus Seneca (c. 4 BCE to 65 CE)

The philosopher, statesman, orator, tragedian, and satirist Seneca the Younger was the leading intellectual of Rome in the mid-first century CE. Born to a wealthy family in Cordoba, Spain, he pursued a career in politics and law in Rome. In 41 CE, emperor Claudius charged Seneca with committing adultery with Claudius' niece and banished him to the island of Corsica. After Claudius was murdered in 54 CE, Seneca and his friends grew powerful. He became tutor and then adviser to the emperor Nero. In 65 CE, his enemies accused him of being an accomplice in the conspiracy of Piso to murder Nero. Ordered to commit suicide, Seneca met death with courage and calm. His vast wealth colored his perspective on food.

Seneca is clear that the purpose of food is to relieve, not arouse, hunger (Seneca 2015, 95.15–18). He argues that a human being's frontal part is virtue itself, whereas the unserviceable and unstable flesh attached to it is a mere repository for food (Seneca 2015, 92.10). Seneca believes that virtue calls for limiting our wants to our basic needs. Our needs are established by nature, and nature desires nothing except a meal. Hunger, he infers, is not ambitious. Hunger is satisfied to stop, and it does not much care what

makes it stop. Once hunger is stopped, only the torments of a wretched self-indulgence look for ways to stimulate hunger after it is sated. Thus, only the vice of self-indulgence drives a person to keep stuffing his filled stomach (Seneca 2015, 119.13–14).

By comparing the size of human beings to those of larger animals, Seneca reasons that we can and should feed ourselves more easily than they do. "Has nature given us such an insatiable maw that although the bodies we are given are of modest size, we yet surpass the largest, most ravenous eaters of the animal world? That is not the case, for how small are our natural requirements! It takes only a little to satisfy nature's demands. It is not bodily hunger that runs up the bill but ambition. Therefore let us regard those who, as Sallust says, 'heed the belly' as belonging to the race of animals rather than of humans" (Seneca 2015, 60.3–4). Ambition causes vicious eating, and to eat viciously is to degenerate from a human being into a beast. Thus, Seneca advises indulging the body only to the extent that suffices for health. One must deal sternly with one's body, lest it fail to obey one's mind. "Let food be for appeasing hunger, drink for satisfying thirst" (Seneca 2015, 8.5).

Food is more welcome to one who is hungry (Seneca 2015, 78.22). Thus, it is wise to know when to stop eating and drinking, as nonhuman animals do (Seneca 2015, 59.13). We ought to eat moderately (Seneca 2015, 114.26–27), not greedily (Seneca 2015, 94.22). Seneca believes that meals ought to be eaten during the customary times of the day (Seneca 2015, 122.9–10) and in the company of others. He recommends reflecting carefully beforehand with whom you are to eat and drink, rather than what you are to eat and drink, for feeding without a friend is the life of a lion or a wolf (Seneca 2015, 19.10).

Seneca notes that luxurious eating causes many complex, manifold diseases and disorders. He criticizes gourmandizing and fancy foods like mushrooms, delicately prepared oysters, mussels, sea urchins, garum (fermented fish sauce), and filleted, deboned mullets (Seneca 2015, 95.25–29). Seneca reports that he abstains from

eating oysters and mushrooms because “These are not food; they are only tidbits meant to entice those who are full to eat some more (which is what the glutton wants, to stuff himself beyond capacity), for they go down easily, and come back up easily too” (Seneca 2015, 108.15).

The most shameful scourge that assails fortunes is the kitchen (Seneca 1989, *Ben.* 1.10.2). Seneca deplores spending lots of money on delicacies. He tells the story of two men bidding against each other to buy a 4½ lb mullet. The winner paid the extravagant sum of 5000 sesterces for the fish (Seneca 2015, 95.42). Even worse, the emperor Gaius Caesar demonstrated supreme vice combined with supreme power when he dined one day at the astronomical cost of ten million sesterces (Seneca 2014, *Helv.* 10.4). “How wretched are the people whose appetite is stimulated only by costly foods! But what makes them costly is not their exquisite flavor or some pleasant sensation in the throat but their rarity and the difficulty of obtaining them. Otherwise, if these people would willingly return to sanity, what need of so many professional skills that serve the belly? What need of imports, or of devastating forests, or of scourging the sea? All about us lie the foods which nature has made available in every place; but these people pass them by as if blind, and they roam through every country, they cross the seas, and though they could allay their hunger at a trifling cost, they excite it at great expense” (Seneca 2014, *Helv.* 10.5). Exotic seafoods and mushrooms require great time, effort, and resources to obtain. Garum requires much time, labor, and resources to produce and import. So, Seneca condemns all such foods as decadent luxuries.

In contrast, he praises Gaius Fabricius Luscinus for happily dining on those very roots and grasses he picked clearing his fields. “Would he have been happier if he had crammed into his belly fish from distant shores, and exotic birds? If he had roused his slow and sickened stomach with shellfish from the upper and lower [Adriatic and Tyrrhenian] seas? If he had arrayed a huge pile of fruits around highly sought-after beasts caught at great loss of hunters’ lives?” (Seneca 2014, *Prov.* 3.6). Importing foods from afar is entirely

unnecessary, and hunting dangerous animals is reckless because locally grown crops are readily available. Thus, only wasteful, dissipated fools demand exotic, imported foods.

Seneca believes that the needs of the body greatly outnumber the needs of the mind. “For the body needs many things in order to thrive, but the mind grows by itself, feeds itself, trains itself. Athletes require a great deal of food and drink, much oil, and lengthy exercises; but virtue will be yours without any supplies or expenses. Anything that can make you a good person is already in your possession” (Seneca 2015, 80.3). The Stoics highly valued self-sufficiency. Seneca commends the mind’s pursuit of virtue because it costs no money and requires no equipment, whereas to build an athletic body requires much food, drink, and time-consuming exercises. He thinks that bodybuilding and the heavy diet that goes with it don’t befit an educated man, because a brawny, bulky body burdens the mind and makes it less agile (Seneca 2015, 15.2–3). Instead, he instructs his friend to set himself a period of days in which he will be content with very small amounts of food, and the cheapest kinds, in order to dispel his fear of frugality (Seneca 2015, 18.5). Seneca contends that fearless, frugal eating makes you a better person than a muscular physique does.

Seneca writes: “I like food that is neither prepared nor watched by troops of servants, not something ordered many days ahead and proffered by many hands, but available and easily so, with no exotic or precious ingredients. This will not run out on any occasion, or be a burden to my budget or my body, or be brought up in vomiting” (Seneca 2014, *Tranq.* 1.6). He reports taking a trip with a friend during which his frugal habits included lunching on dried figs, sometimes with bread (Seneca 2015, 87.3).

Seneca’s thoughts about and experience with vegetarianism were complex. The belief that it is wrong to eat animals was shared by the prominent ancient Greek philosophers Pythagoras, Empedocles, Theophrastus, and perhaps Plato. In his youth, Seneca was taken with the philosophy of Pythagoras. Seneca’s teacher Sotion explained both Pythagoras’ and Sextius’ reasons for

abstaining from animal food. “Sextius held that a person could get enough to eat without resorting to butchery; and that when bloodshed is adapted to the purposes of pleasure, one develops a habit of cruelty. He also used to say that one should pare away the resources of self-indulgence, and he offered reasoning to show that variety in food is alien to our bodies and detrimental to health” (Seneca 2015, 108.17–18). Pythagoras, on the other hand, believed in the kinship of all living things and held that souls never die but only transmigrate from one animal’s body, when it dies, into the next, whether it be that of a human or a nonhuman. “Pythagoras instilled in humankind a fear of wrongdoing – more specifically, of parricide. For if some spirit related to them happened to be dwelling in a given body, they might, without realizing it, assault the soul of their parent with the knife or with their teeth” (Seneca 2015, 108.19). Sotion reasoned that if these beliefs are true, then abstaining from animal foods means not harming anyone. If they are false, then vegetarianism is economical. Seneca, persuaded by Sotion of the savagery of eating flesh as lions and vultures do, adopted the habit of abstaining from animal food. He says this diet became easy and pleasant for him and made his mind livelier. Later, however, abstinence from animal food was seen as adherence to religions of foreign origin banned by the emperor. So, when his father asked him to give up his vegetarian diet, Seneca complied. He returned to a temperate but nonvegetarian diet.

For Seneca, then, Stoicism calls for simple, simply prepared, frugal meals of foods that are close at hand. “Our aim is to live in accordance with nature, is it not? This is contrary to nature: tormenting one’s body, swearing off simple matters of grooming, affecting a squalid appearance, partaking of foods that are not merely inexpensive but rancid and coarse. A hankering after delicacies is a sign of self-indulgence; by the same token, avoidance of those comforts that are quite ordinary and easy to obtain is an indication of insanity. Philosophy demands self-restraint, not self-abnegation” (Seneca 2015, 5.4–5; cf. 78.22–24). Seneca concludes that moderate, unfussy eating does not require self-deprivation or fasting.

Gaius Musonius Rufus (c. 20–30 to as late as 101 CE)

Born in Volsinii, Italy, Musonius was a Roman knight (*equus*), the class of aristocracy ranked second only to senators. He taught and practiced Stoicism in Rome and was exiled first by Nero upon discovery of the conspiracy led by Piso, and later by Vespasian. He had a considerable following during his life. His teachings survive as 32 apothegms and 21 longer discourses, all preserved by others.

Emphasizing the importance of daily practices, Musonius held that mastering one’s appetites for food and drink is the basis for self-control, a vital virtue. He agrees with Seneca that the purpose of food is to nourish and strengthen the body and to sustain life, not to provide pleasure. Digesting our food gives us no pleasure, and the time spent digesting food far exceeds the time spent consuming it. It is not consumption but digestion that nourishes the body. Therefore, he reasons that the food we eat serves its purpose when we’re digesting it, not when we’re tasting it (Rufus 2010, *Lecture* 18).

Musonius argues that the proper diet is lacto-vegetarian. These foods are least expensive and most readily available: raw fruits in season, certain raw vegetables, milk, cheese, and honeycombs. Cooked grains and some cooked vegetables are also suitable for humans, whereas a meat-based diet is too crude for human beings and is more suitable for wild beasts. Musonius thought that those who eat relatively large amounts of meat seem slow-witted (Rufus 2010, *Lecture* 18).

We are worse than nonhuman animals when it comes to food, Musonius believes, because we are obsessed with embellishing how our food is presented and fuss about what we eat and how we prepare it merely to amuse our palates. Moreover, too much rich food harms the body. So, he judges that gastronomic pleasure is undoubtedly the most difficult pleasure to combat (Rufus 2010, *Lecture* 18). Consequently, he, like Seneca, rejects gourmet cuisine and delicacies as a dangerous habit. He regards craving gourmet food to be most shameful and to show a lack of temperance. Musonius thinks that those who eat inexpensive

food can work harder; are the least fatigued by working; become sick less often; tolerate cold, heat, and lack of sleep better; and are stronger, than those who eat expensive food (Rufus 2010, *Lecture* 18). He concludes that responsible people favor what is easy to obtain over what is difficult, what involves no trouble over what does, and what is available over what isn't. These preferences promote self-control and goodness.

Epictetus (c. 55 to c. 135 CE)

Epictetus was born a slave in Hierapolis in what is today southwestern Turkey. He traveled to Rome where his master permitted him to attend the lectures of Musonius. After he was freed, Epictetus practiced and taught Stoicism. When the emperor Domitian, who suspected them of republican sympathies, expelled all philosophers from Rome, Epictetus moved to Nicopolis on the northwestern coast of Greece. There he founded a school which earned an outstanding reputation. His student Arrian recorded Epictetus' teachings in the *Discourses*, four books of which survive, and a compendium titled the *Handbook*.

Epictetus' experiences as a slave inform his views of Stoicism and food. Real slavery, he believes, is living in fear. So, he urges his students to get rid of all fears regarding eating. When a student frets about being too poor to be able to eat, Epictetus scolds him for lacking confidence in being able to fend for himself as successfully as slaves and runaways do. A worrywart who fears starving must believe he is stupider and less resourceful than irrational beasts, all of whom are self-sufficient and provided with food and a mode of survival adapted to and in harmony with their nature (Epictetus 2008, *Disc.* 1.9.8–9). Epictetus notes that neither runaway slaves nor old beggars starve, so we have no good reason to worry that our food will run out. Instead, we should concern ourselves with becoming good. "Does any good man fear that food may fail him? It does not fail the blind, it does not fail the lame. Shall it fail a good man?" (Epictetus 1995, *Disc.* 3.26.27). For Epictetus "dishonor does not consist in not having anything to eat, but in not having reason enough to exempt you from fear or

sorrow" (Epictetus 1995, *Disc.* 3.24.116). A good person uses reason to overcome fear and sorrow.

Epictetus believes that god (nature) both provides and takes away all our material possessions. "It is another who gives you food, and property, and can also take them away, and your paltry body too. You should, then, accept the material you are given and set to work on it" (Epictetus 1995, *Disc.* 2.5.22). And if god no longer provides food, then this could only mean that, like a good general, god has given the signal to withdraw, god is sounding the recall, opening the door, and saying to "Come" (Epictetus 1995, *Disc.* 3.13.13–14). Epictetus says he will obey while speaking well of his leader and praising his works (Epictetus 1995, *Disc.* 3.26.29). If starvation ever does become inevitable, the Stoic accepts it calmly. In contrast, the non-Stoic weeping about going hungry foolishly makes himself a slave to his fear. "No sooner have you eaten your fill today than you sit and start worrying about where tomorrow's food will come from. Look, if you get it, slave, then you will have it; if not, you will depart this life: the door is open. Why complain? What place is there left for tears?" (Epictetus 2008, *Disc.* 1.9.19–20). Thus, Epictetus sees no reason to fear starving to death. God will either provide us food or not. If so, then there's nothing to fear. If not, then there's no dishonor in exiting life when god decides it is our time to die. After all, only mortals need food.

Epictetus agrees with Seneca and Musonius that the purpose of eating is not to feel pleasure (Epictetus 1995, *Disc.* 3.24.37–38). We should take only what the body strictly needs in food, drink, clothing, and shelter and eliminate luxury and ostentation altogether (Epictetus 2008, *Ench.* 33.7). Each gift in our lives is granted to us only for the time being, neither irrevocably nor forever, "like a fig or a bunch of grapes in the appointed season; and if you long for it in the winter, you are a fool" (Epictetus 1995, *Disc.* 3.24.86). We must adapt our desire to what is available when it is available. Also, Epictetus denies that the conflicting opinions concerning food of Jews, Syrians, Egyptians, and Romans could all be right (Epictetus 2008, *Disc.* 1.11.12–13). Those who have truly digested their philosophical principles show it by eating, drinking, dressing,

marrying, having children, and being citizens, as a human being should (Epictetus 1995, *Disc.* 3.21.1–5).

Epictetus does not share Musonius' vegetarianism. He declares that "god created some beasts to be eaten, some to be used in farming, some to supply us with cheese, and so on" (Epictetus 2008, *Disc.* 1.6.18). He mentions that dinner guests ought to take only their polite share of the roast (Epictetus 2008, *Disc.* 2.4.8). Like Seneca, however, Epictetus commends strategic abstinence in order to discipline one's desires. "Practice living as an invalid at one time, so that you may live like a healthy man at another. Abstain from food. Keep to water. Abstain from desire altogether for the present, to exercise it later, in accordance with reason" (Epictetus 1995, *Disc.* 3.13.21). Thus, Epictetus calls for eating and drinking only what is strictly necessary, eliminating all luxuries, and vanquishing all worries about food.

Marcus Aurelius Antoninus (121 to 180)

Born in Rome to a prominent family of Spanish ancestry, Marcus' father died when he was young. Frank, sincere, sensitive in character, and austere, Marcus impressed the emperor Hadrian, who nicknamed him *Verissimus*, "the most truthful." Hadrian arranged for his successor, Antoninus Pius, to adopt Marcus. He learned rhetoric, grammar, philosophy, and law from the best teachers of his day. His thought was deeply influenced by Epictetus. Marcus reigned as emperor from 161 CE until his death. During years on campaign on the empire's northern frontier, he wrote a series of private reflections on time, transience, self-improvement, and his place in the universe. These exercises in philosophical therapy came to be called the *Meditations*.

In the *Meditations*, Marcus often reminds himself to strip away the illusions that beguile people into craving fame, riches, luxuries, and carnal pleasures. For example, when beholding a fancy plate of meat or a pricey glass of wine, some see fabulous delicacies and swoon. But Marcus cautions himself to see what they really are. "Like seeing roasted meat and other dishes in front of you and suddenly realizing: This is a dead fish.

A dead bird. A dead pig. Or that this noble vintage is grape juice. . . . Perceptions like that – latching onto things and piercing through them, so we see what they really are. That's what we need to do all the time – all through our lives when things lay claim to our trust – to lay them bare and see how pointless they are, to strip away the legend that encrusts them. Pride is a master of deception: when you think you're occupied in the weightiest business, that's when he has you in his spell" (Aurelius 2003, vi. 13). To gourmandize meat is to fool yourself into believing that it is more than a corpse. To glorify sumptuous food and drink is to be bewitched into cherishing calories. According to Marcus, calories are garbage compared to a sound, righteous mind.

Summary

The Stoics defined the goal in life as living in agreement with nature. For human beings, this means especially living in agreement with reason. The perfection of reason is virtue, which includes the virtues of wisdom and temperance. Living wisely and temperately, they reasoned, rids us of fears, including fear of poverty, illness, hunger, and not getting what we want to eat. The wise and temperate know that simple, inexpensive foods in moderate amounts produced locally are easy to get and prepare, healthy for the body, and good for the mind. Thus, Stoicism dictates frugality of diet and the rejection of ambitious eating, gluttony, luxuries, delicacies, and gustatory extravagance. Some Stoics favor vegetarianism. All Stoics think it wise to limit eating and drinking to strict bodily need and to eradicate all food anxieties.

Sub-Saharan African Agriculture

Steven Haggblade

[Africa](#); [Agriculture](#)

Introduction

Agriculture employs two-thirds of Sub-Saharan Africa's (SSA) workforce and a majority of the continent's poor (IFPRI 2004). As a result, agricultural productivity growth offers a singularly powerful lever for raising incomes and reducing poverty across the continent (Thirtle et al. 2003; de Janvry and Sadoulet 2010; Christiaensen et al. 2010). Recent estimates from Kenya and Rwanda, for example, indicate that a 1% increase in national income coming from the agricultural sector leads to three to four times as much poverty reduction as comparable income gains in non-agricultural sectors of the economy (Diao et al. 2012).

Agricultural growth is, likewise, a key driver of economic growth and structural transformation. Because agriculture accounts for 25% of Sub-Saharan Africa's gross domestic product, and up to 50% in poor countries, productivity gains in agriculture translate directly into broad-based per capita income gains (IFPRI 2004; Diao et al. 2012). Over the long run, improved agricultural technology, agronomic practices, and marketing systems will enable a minority of well-managed smallholder farms to transition into high-value commercial agriculture. In contrast, the majority of today's smallholder farmers will follow an alternate pathway, as elsewhere, gradually exiting agriculture in favor of nonfarm occupations. But in Africa, as in other settings before, this exit will require prior broad-based agricultural

productivity growth on small family farms (Lipton 2005). Even the continent's many non-commercial, primarily subsistence farmers require early, sustained productivity gains in agriculture so they can free their children from farm labor obligations, generate the surpluses necessary to send them to school, and help them transition into successful nonfarm career trajectories over the next generation (Chapoto et al. 2013).

Despite the importance of agricultural growth to African economies and to the welfare trajectories of its people, farm productivity remains generally low in SSA. Labor productivity, as measured by the value of agricultural output per worker, stands at roughly two-thirds of the level prevailing in developing Asia. Land productivity, as measured by cereal yields, lies closer to one-half of the levels attained in Asia and Latin America (Table 1).

Why has African agriculture underperformed? In part, Africa's historical land abundance has allowed African governments to underinvest in agricultural research, extension, and other key drivers of agricultural productivity growth. For many decades, African leaders have spent half as much (per \$100 of agricultural output) as Asian countries on the core public goods that drive agricultural growth – rural roads, irrigation systems, agricultural research, and extension (World Bank 2007). Donors have, likewise, contributed to low agricultural spending, cutting aid flows for

African agriculture in half, from over US\$2 billion to around \$US1 billion per year between the mid-1980s and the early 2000s (GAO 2008).

Recent world events have restored interest in Africa's agricultural potential. Back-to-back world food crises – in 2008 and 2011 – have focused the attention of African leaders, donors, and outside investors on the considerable potential and importance of Africa farming. Food riots from West Africa to Mozambique have reminded African political leaders that food security remains critical for political stability, lending new urgency the African leaders' Maputo commitment of 2003 to increase their budget allocations for agriculture from 6% to 10% of total spending as part of the AU's Comprehensive Africa Agricultural Development Programme (CAADP) (AU/NEPAD 2003; Fan et al. 2008). Donors have likewise placed agricultural growth at the top of the aid agenda. After two decades of neglect, when global aid for African agriculture fell roughly in half, the 2009 Group of Eight (G-8) meeting in L'Aquila, Italy, committed \$20 billion over 3 years for agricultural development and related efforts to reduce world hunger (G-8 2009; G-20 2010). Private investors have also piled onto the bandwagon. In 2009, large agribusiness investors laid claims to nearly 40 million hectares of African farmland, greater than the agricultural land of Belgium, Denmark, France, Germany, the Netherlands, and Switzerland combined (Deininger and Byerlee 2012). Highly publicized large-scale land investments in Africa by institutional investors have focused world attention on Africa's considerable unexploited agricultural potential and on the ethical issues involved in allocating these valuable resources among domestic and international constituencies.

As policy attention returns to focus on African agriculture, this entry aims to explore key opportunities and key challenges facing African farmers and policy makers. The entry begins by highlighting two key opportunities that will likely drive future interest and investments in Africa's agricultural and food system growth. Discussion then turns to a series of structural and ethical challenges that policy makers and stakeholders will need to address in order to realize Africa's considerable yet under-exploited agricultural potential.

Sub-Saharan African Agriculture, Table 1 Productivity differentials across regions

	Sub-Saharan Africa	Developing Asia	Latin America
Value of agricultural production (US\$)			
Per agricultural worker	315	457	3018
Per hectare	140	1111	381
Cereal yields (tons/ha)	1.4	3.1	3.9

Seizing Opportunities

Growing Urban Markets

Africa's food markets will grow rapidly over the coming decades. Projections suggest that Africa will become a majority urban continent by 2030 when urban population surpasses that in rural areas (UN 2012). As a result, marketed food shares will grow more rapidly than overall population. Consumption patterns will also change dramatically. Rising urbanization and growing per capita incomes will translate into dramatically increased demand for processed, packaged, and prepared foods. Because of increasing urban demand for marketed foods, the post-farm segment of Africa's food systems will grow twice as fast as farm production over the coming 40 years (Haggblade 2011). Demand for nutrient-dense high-value foods such as dairy products, meat, fresh fruits, and vegetables will increase as well. Food products, which accounted for about three-fourths of total agricultural output in the year 2000, will increasingly dominate agricultural markets (Diao and Hazell 2004). As a result, domestic and regional food markets within Africa offer farmers their largest single market opportunity over the coming decades.

Spatially, growing domestic food markets will trigger rapid growth in the rural towns that house assembly markets linking agricultural production zones with major urban centers. In terminal markets, the often uncontrolled growth of Africa's large cities rapidly engulfs surrounding peri-urban zones, while growing marketed volumes and commercial traffic quickly outgrow the existing capacity of urban transport arteries and market infrastructure. As a result, early investments in urban planning, zoning, road quality, and urban food market infrastructure and management systems can significantly improve the efficiency of urban wholesale markets, reducing losses and improving sanitation and public health. A focus on market improvements in Africa's rapidly growing secondary cities offers early opportunities for quick wins.

Cross-border flows of food commodities will, likewise, assume increasing importance as Africa's urban food markets grow. In part, the

growing opportunities for intra-African regional trade arise because the partition of Africa has left 25% of its countries landlocked. Moreover, arbitrary boundaries established during the colonial period result today in complex jigsaw puzzle of political borders that often separate breadbasket regions from the deficit market they would most naturally serve (Haggblade 2013). Livestock surpluses from West Africa's Sahel serve coastal markets across the region, while South Africa's consistent maize surpluses serve intermittently deficit markets throughout Eastern and Southern Africa. These complementarities motivate growing interest in knitting together intra-African agricultural markets through regional trade agreements and strategic development corridors (ECOWAS 2004; Hazell 2012; World Bank 2012). Expansion of the East African Community (EAC) in 2007 provides a recent example of growing African interest in regional economic integration.

Supply Responsiveness: Surplus Land, Yet Growing Land Pressure in Communal Areas

Historically land-surplus, Sub-Saharan Africa today contains 45% of the uncultivated potential cropland in the world (Deininger and Byerlee 2012). The continent's 200 million hectares of uncultivated, unforested potential cropland roughly equals the 210 million hectares currently farmed. Potentially, African farmers can double cropped area. These large blocks of underutilized land have triggered a worldwide land rush since the first world food crisis of 2007–2008, as large agribusiness firms have scrambled to secure access to fertile land. In 2009 alone, African governments allocated 39 million hectares of cropland to large institutional investors (Deininger and Byerlee 2011).

Africa's generally egalitarian land distribution and low levels of rural landlessness have historically provided a broad safety net for its rural populations. Unlike large Latin American countries, where fewer than 15% of farmers control over 80% of cropland, large farms of over 500 hectares control at most 5–10% of cropland in most SSA countries (Lipton 2012). The Republic of South Africa and other settler economies in

Kenya, Rhodesia, and Zambia are the notable exceptions due to historical policies providing preferential treatment and special land allocations for large farms. In the presence of growing demographic pressure over the past four decades, average farmland per capita in communal areas has fallen by about 40% (World Bank 2007; Eastwood et al. 2010; Jayne et al. 2012). Paradoxically, Africa's dual land tenure system has resulted in growing land pressure inside communal areas while at the same time governments are allocating large blocks of new land, outside the communal areas, to large institutional investors.

Given current low yields and surplus land, African farmers can potentially unleash an enormous agricultural supply response. Moving from yields of 1 ton per hectare to 2 tons is quite feasible (InterAcademy Council 2004). Renewed investments in agricultural research, extension, regional input supply platforms, and rural roads provide the key to closing this yield gap.

The second key ingredient for enabling this supply response revolves around land consolidation in communal areas and the opening up of new lands in ways that facilitate farmer transitions from small-scale holdings in communal areas to medium and large farms on existing or newly developed state lands. Much of the recent furor surrounding "land grabs" by large institutional investors revolves around ethical concerns, particularly the perception that outsiders may be receiving special access to large land blocks, while progressive smallholder farmers in communal areas do not enjoy comparable opportunities to graduate to larger-scale farming (Deininger and Byerlee 2011). Several possible models exist for making new farmland available to successful smallholders. Development of new farm blocks with roads, electricity, and communications infrastructure and with mixed farm sizes offers one model under which large farms serve as anchor tenants enabling cost-effective recovery of initial infrastructure investments while at the same time medium and small farms relieve pressure on communal lands by providing outlets for the more commercially oriented smallholders to grow. Together, investments in agricultural productivity and improved land allocation and tenure systems

offer prospects for unleashing a substantial supply response from African farmers.

Confronting Key Challenges

Small Countries

Africa faces an endemic small-country problem. Sub-Saharan Africa houses 49 countries, half with populations under ten million. The continent's patchwork of highly arbitrary, inherited political borders constrains agricultural growth in several key ways: (1) hampering technology transfer and disease control; (2) cutting the continent's many breadbasket zones from the cross-border markets they would most naturally serve; (3) increasing transport and transaction costs that, in turn, lower farmgate prices and raise input costs such as fertilizer and seed; (4) and limiting sale economies in research, input supply, and output marketing (Haggblade 2013).

Research and development on improved agricultural technologies remains critical for accelerating agricultural growth. Yet new agricultural technologies spread slowly in Africa where multiple small countries partition common agroecological zones. West Africa's root crop zone, for example, cuts across ten different countries while its millet belt transits seven. As a result, differing languages, phytosanitary controls, and seed certification processes at each border constrain the free flow of new technologies. In addition, agricultural pests and diseases – such as cassava mealybug, trypanosomiasis, and foot and mouth disease – powerfully affect agricultural productivity. Because these pests easily cross political borders, carried on the wind and wild animals, individual countries face chronic difficulties in raising farm productivity in the absence of effective regional collaboration.

Equally constraining, political borders frequently separate Africa's many surplus food production zones from cross-border deficit markets they would most naturally serve. They separate surplus millet and sorghum producers in southern Mali and Burkina Faso from deficit markets in half a dozen surrounding countries; surplus maize grown in South African from deficit

markets throughout southern and eastern Africa; breadbasket zones in northern Mozambique and southern Tanzania from intermittently deficit markets in Malawi, Zimbabwe, and eastern Zambia; and livestock exporters in Mali, Mauritania, and Niger from coastal markets across West Africa.

The resulting high transaction costs restrict trade flows, raise transportation costs, disrupt market signals, and reduce farmer incentives to expand food production in breadbasket regions. Poor perimeter infrastructure and a high density of border controls contribute to exceptionally high transport costs in Africa, roughly four times higher per ton kilometer than in other developing regions (World Bank 2010). Along major West African trade corridors, the informal rent seeking that accompanies cross-border transactions results in cattle traders paying twice as much for cross-border shipments of cattle as for domestic transportation, despite better transportation infrastructure (Borlaug 2012). Similarly, analysis of food price differentials along the Democratic Republic of the Congo-Rwanda border suggests that border controls enlarge spatial price spreads in food prices by the equivalent of a staggering 1600 km in market distance (World Bank 2012). These high transaction costs, in turn, reduce farmgate prices, raise input costs, and increase consumer prices in cross-border markets.

Economies of scale offer the potential to lower unit costs of most agricultural inputs, including electrical power, banking, insurance, transport, communications, agro-processing, and fertilizer distribution. But, conversely, diseconomies of scale result when a constellation of separate, small countries must administer, equip, and staff individual national power grids, research and agricultural education systems, and agribusiness networks. Given the considerable economies of scale in electric power generation, small African countries pay electric generation costs roughly double what would be necessary under large-scale power plants, regional power pools, and regional power-sharing arrangements (World Bank 2010). Similarly, prices of imported fertilizer increase roughly 30% under the current patchwork of multiple small-country markets and small lot purchases compared to what would be attainable

under regional systems of bulk fertilizer imports coupled with intra-Africa regional trade (Gregory and Bumb 2006; Morris et al. 2007). Economies of scale also exist in agricultural research and education, where investments in specialized staffing and equipment all become possible. “Because of small country size, agricultural research systems in Sub-Saharan Africa are fragmented into nearly 400 distinct research agencies, nearly four times the number in India and eight times that in the US. This prevents realizing economies of scale in research” (World Bank 2007, p. 168). For Africa’s many small countries, “Very often, the only viable – and efficient – solution is regional collaboration” (Beintema and Stads 2011, p. 28).

In general, feasible solutions to the agricultural inefficiencies embedded in Africa’s patchwork of small countries revolve around regional collaboration in scientific research, education, trade, power generation, and corridor development programs (Haggblade 2013).

Sustainable Intensification

In past generations, Africa’s agricultural growth has relied on area expansion, while farmers have maintained soil fertility through shifting cultivation, natural fallows, and soil mining. Low rates of fertilizer application – less than 10 kg/ha in Africa compared to 100 kg in Asia – have led to decades of soil mining, generating annual nutrient losses of over 20 kg of nitrogen, 15 kg of potassium, and 2.5 kg of phosphorus per hectare from African soils (Smaling et al. 1997; Morris et al. 2007).

Looking forward, this system will become increasingly unsustainable. Continued demographic pressure on farmland, particularly in communal areas, will stimulate incentives to intensify farm production. These growing land pressures have given rise to a growing body of research and experimentation on alternate methods for sustainable soil fertility management (Sanchez et al. 1997; Conway 1999; Pretty and Hine 2001; Morris et al. 2007; Haggblade et al. 2010). Most of these efforts involve increased doses of mineral fertilizer coupled with improved soil and water management practices, typically involving some combination of water harvesting, dry season minimum tillage, crop residue management,

leguminous crop rotations, organic soil amendments, and short, managed fallows with selected leguminous shrubs.

In the past, most agricultural research in Africa has focused on breeding improved varieties of crops and livestock and delivering improved input packages to farmers. In the future, improved agronomic practices will become increasingly important. Given the diversity of farming conditions prevailing in rural Africa, future farm technology development will need to include site-specific adaptive research coupled with strong farmer involvement in design and testing.

Changing Structure of Agricultural Education and Research

Increasing urbanization and changing food consumption patterns hold important implications for the human skills required to manage Africa's changing food systems. To scale up processing of local foods such as cassava, maize, sorghum, yam, and banana from artisanal to industrial scales, the food industry will need to undertake research on the biochemistry of basic food fermentations and on nutritional outcomes under alternate processing and packaging technologies. To serve increasing demand for packaged, processed, and prepared foods, Africa's future food system will require a steady flow of trained scientific and technical manpower trained in the science of increasingly input intensive farm production, feed industries, storage systems, supply chain management, and food processing industries (Haggblade 2011).

In response, Africa's agricultural education and research institutions will need to adapt in order to effectively serve this changing food system. In the past, Africa's agricultural universities have trained primarily extension staff and researchers for the public sector. In the future, they will need to prepare students for private sector employers in post-farm segments of the supply chain. Africa's agricultural research and education institutions will increasingly need to build expertise in the post-farm areas of food processing, storage, food biochemistry, and food safety in order to prepare students with skill sets

required by the continent's rapidly expanding private agribusiness firms. This institutional double pivot – from public to private sector clients and from on-farm to post-farm segments of the food system – will require a major shift in faculty skill sets, in laboratory facilities, and in systems for actively engaging with private sector employers in the food system (Minde 2012).

Financing the Public Goods Required for Agricultural Productivity Growth

African governments have historically underinvested in the public goods that drive productivity growth in agriculture – rural roads, irrigation systems, agricultural research, education, and extension. While transforming agricultural countries in Asia and Latin America have invested 10% of agricultural GDP in agricultural support institutions and rural infrastructure, African governments have spent less than half as much over many decades (World Bank 2007, p. 41). During the early years of their Green Revolution, India and other Asian countries spent 10–20% of their total government budgets on agriculture, investing heavily in agricultural research, extension, agricultural education, irrigation, and rural roads (Lipton 2012; Hazell 2012). In contrast, African governments currently spend an average of only about 6% of their budgets on agriculture and livestock. As a result, over the three decades between 1970 and 2000, Africa's spending per agricultural scientist fell roughly in half (Beintema and Stads 2006).

Given the high returns to public investments in agricultural research, rural roads, and related public goods, African leaders will need to substantially increase the quantity and quality of their agricultural spending (Fan 2008). While a handful of African governments have delivered on their Maputo commitment to increase public investments in agriculture, most have not yet done so (Fan et al. 2008).

Summary

Agricultural growth over the next generation will be critical to Africa's efforts to accelerate

economic growth and achieve broad-based poverty reduction. But where will the political will come from to fund regional agricultural research and regional trade corridors; reform agricultural research, education, and extension systems; and finance the additional public goods necessary for driving agricultural productivity growth? Skeptics might argue that in the year 2013, 10 years after the AU's commitment to raise funding for agriculture from 6% to 10% of total spending, only a handful of African governments have met this goal. Donor commitments of additional billions in funding for African agriculture have likewise faltered since 2009, in the face of an international financial crisis, recessions in the major donor countries, and severe budget crises in Europe and the USA. As a result, Africa's public sector underinvestment in agriculture persists.

In contrast, the private sector has responded with alacrity to rising food and energy prices by investing heavily in African farmland. This new scramble for African farmland by large domestic and foreign investors has raised alarm bells and elicited considerable press coverage in Africa and abroad. Many observers fear that large estates may displace opportunities for commercial smallholders to expand while at the same time diminishing rural employment opportunities through premature mechanization. These highly publicized political and ethical debates may, nonetheless, prove productive if they spur public sector action and motivate African governments and donors to deliver on their prior commitments to agriculture.

African governments and donors, diverted by recent recessions, political turmoil, and budget crises, now have the opportunity to restore their funding commitments to agriculture, thereby enabling Africa's farmers to seize the considerable opportunities available in Africa's rich natural resource base and growing regional markets. Looking forward, a program of vigorous investment in the public goods that drive agricultural productivity growth and market development offers Africa its best chance for rapid, broad-based poverty reduction.

Introduction

Subsistence orientation is a term to describe the practice of centering economic activities around the production of subsistence, the material and immaterial conditions of human life. Food, as a basic necessity of human survival, as well as a fundamental element of identity and culture, is an essential part of subsistence. Although often associated with poverty, the production of subsistence makes up the foundation of any economy and culture, yet it is differently organized depending on the dominant relations of production (Veronika Bennholdt-Thomsen and Mies 1999).

Mother-Child Relationships

Human life starts within a pure subsistence economy. A mother dispenses nutrients and oxygen through the placenta and the umbilical cord and the baby receives nourishment. During gestation, this giving and taking occurs free from expectations of reciprocity or compensation. Biology does not allow for any other way. The sole purpose of this gift-economy between the mother and her child is the survival and development of the fetus, the reproduction of life. While the mother may procure her own food as commodities in a market economy, once it enters her body, it decommodifies and turns into a gift for the yet-to-be-born.

After birth, this relationship tends to persist. The baby continues to receive nourishment for free from the mother, usually through breastfeeding. Even when infant formula is used as a substitute, the newborn receives it as a gift. As the baby grows into the culture into which it is born, social norms start to shape the relationship between the child and its parents. While these norms differ from culture to culture, they are directed to the subsistence of everyone involved. Even within a capitalist market economy, the goods and services that are exchanged within a family do not usually come with a price tag. Toward the end of one's life, it is customary in most cultures that children will take care of their aging parents. That way, involuntarily, every life starts within a subsistence economy, which often will be carried forth until death.

Hunter-Gatherer Societies

In hunter-gatherer societies, this primal subsistence economy between mothers and their children is extended to the entire community. These societies are usually made up by small communities based on kinship and social alliances. Land and other sources of subsistence are held and managed in common. Foods and other gathered goods tend to be redistributed among community members in an egalitarian fashion. Traditionally, most work afforded on a daily basis would be spent on the procurement (through hunting, fishing, and gathering) and preparation of food. The

accumulation of surplus beyond immediate needs in an environment that proved to be bountiful is both unnecessary and counterproductive to a nomadic lifestyle, and thus commonly avoided by reducing work hours or feasting of excessive foodstuffs.

Gifting is central to the economy of most hunter-gatherer societies. Food is gifted by nature, and the recipients pass on these gifts to the members of their community who are in need of it. In the indigenous traditions of the Americas, the Earth or Nature is seen as a woman that unconditionally provides all living beings with the things they need, just as a mother feeds her baby unconditionally. Animals and plants give their life voluntarily as it is their purpose to sustain someone else's life. From this perspective, natural products are received as gifts and to be used with gratitude and humility, rather than extracted and appropriated as resources. This gifting, then, also becomes the model for interhuman relationships, in that the abundance provided by nature can only be passed on to others as gifts (Kimmerer 2013).

Although often portrayed as poor and constantly on the brink of death, Marshall Sahlins (Sahlins 1972) describes hunter-gatherers as the *original affluent society*. Low consumption levels allowed hunter-gatherers to fulfill their needs with only 3–5 h of daily labor in production. While this observation has been challenged in its universalism, it was instrumental in shifting the attention of ethnographers toward the effective and culturally rich subsistence activities of hunter-gatherers.

Over the course of history, most hunter-gatherer societies have either adopted agriculture or have commonly been dispossessed and displaced. As a result, hunter-gatherer communities today find themselves on less productive or disturbed land, which greatly curtails their ability to subsist on it. Consequently, many hunter-gatherers have augmented their livelihood with agriculture and trade, while others have become dependent on government support.

Peasant Farming

Peasant farming is a type of agriculture that is primarily directed at the reproduction of the farm as the source of livelihood for the farm family.

Being the predominant form of agriculture in many developing countries, the primary objective of keeping the farm going and feeding the family on it is pervasive even among farmers in developed countries. It has long been predicted that the peasantry would cease to exist under capitalist relations of production, yet the continued persistence of peasant farms has cast doubts on this prophecy. The relative number of people engaged in farming has plummeted and industrial farming has been steadily on the rise over the last century, in particular in industrial countries, but it is estimated that 84% of the farms worldwide are small-holdings with less than two hectares (Lowder et al. 2016) providing food to about 70% of the world's population (ETC 2009). Although size is an imprecise predictor of subsistence orientation, it can be assumed that most of these operations are peasant farms. Focusing on Southeast Asia, James Scott (1976) describes “subsistence ethics” as a central element of the peasant worldview. He found that the overall objective to keep the farm going as a source of livelihood leads peasants to avoid risks like a new crop or technology unless proven successful in the local environment of the farm. On the community level, Scott observed that peasants regard subsistence as a “fundamental social right,” which mandates redistribution of wealth to those in need.

Even on many larger farms whose products are predominantly sold as commodities, peasant farming continues to exist as an organizing principle that farmers try to approach against pressures to expand (van der Ploeg 2008). For example, many farms keep a kitchen garden or additional livestock for self-provisioning. Another common strategy is to invest in the health of the soil or one's herd, beyond what would be necessary for short-term economic gain, with the goal to improve the reproductive capital of the farm.

In recent decades, there has been a strong movement toward local agriculture in North America and Europe. Farmers' markets, u-pick farms, and community supported agriculture are all on the rise. Community gardens bring farming into the cities and blur the lines between consumers and producers. Although the people in

these new and rediscovered arrangements come from vastly diverse backgrounds, and most of them would reject the term peasant as part of their identity, the local food movement aims to put the provisioning of people with food back into the center of agriculture.

Subsistence in Neighborly Communities

Personal relationships among neighbors are commonly based on subsistence-oriented transactions. In many parts of the world, it is customary to ask a neighbor for help, such as looking after the children or borrowing an ingredient critical for a favored meal. Some research suggests that neighborhood ties are the strongest where people actively engage in subsistence production, which provides them with much valued goods and skills that they can share within the local community. For example, in a German rural small town, Baier et al. (2005) observed a web of mutual responsibilities and support that is based on the celebration of foods prepared at home and shared at various community events. The Appalachian Mountains in the Eastern United States of America are well-known for their proud canning culture. The sharing of home-made preserves, such as pickled produce, jam, and jellies, is a central element of many community events, despite mass-produced alternatives being readily available. In Morocco, women in both cities and villages gather at the *faraan*, a public oven, to bake their bread and pastries, share the latest news, and build community ties (public bakehouses used to be common throughout Europe's villages). Globally, the increased interest in community gardens implies a desire to build community through a traditional, food-oriented subsistence activity, within socioeconomic environments that are not conducive for neighbors to meet in any other way. As these selected examples demonstrate, subsistence practices around food are not only valued in local communities, but critical to the reproduction of social ties and the creation of social capital. Ferdinand Tönnies and Harris (Tönnies and Harris 2001) uses the term *Gemeinschaft* to describe such communities that are built on interpersonal ties and codependence in satisfying subsistence needs.

Subsistence in the City

Although the city as a form of social organization depends on a colonial relationship with rural places that provide the city with food for its subsistence, there exist spaces within the urban fabric that are directed at the subsistence of a local community. In many instances, these are responses to dire economic conditions in which subsistence techniques are used to secure survival. Especially in the slums in developing countries, but also in battered, postindustrial cities in developed countries, marginalized communities turn to urban gardening and animal husbandry to provide themselves with food. The residue of industrial overproduction is gleaned from landfills and trashcans. Political movements, such as the Black Panthers or the American Indian Movement in the United States of America, started as self-help groups that intended to satisfy basic subsistence needs, such as food, for its membership in large cities. These forms of urban subsistence production are not a matter of free choice but a necessity under conditions of unemployment, poor social security, and dispossession. Yet, often they are also expressions of cultural continuity. Many of the food-growing slum dwellers in the third world are former peasants who moved to the cities and brought with them the skills to produce food and the moral obligation to provide for their community. When Puerto Rican immigrants occupied vacant lots in New York's Lower East Side to start the city's first community gardens, they did so not just for the food, but also to surround themselves with plants and a community based on shared subsistence work that they grew up with but came to miss in Downtown Manhattan.

The 1960s countercultural movement initiated a new set of urban subsistence networks. Linking material needs with political goals, students, and other young urban dwellers with largely middle-class backgrounds tried to redefine what living in the city could be, stripping the urban economy of some of its exploitive relationships with the rural hinterland. Housing and food cooperatives were founded with the goal of providing one's community with food outside of capitalist market relations. Urban gardens were started to shorten food miles, bring fresh produce to the city, and

commonly to point to the injustice of leaving urban space unused while human subsistence needs could be satisfied with it. Self-identifying dumpster divers or freegans recover discarded, yet still palatable food, in order to redistribute it and highlight the ecological and social problem of food waste and overproduction. Although many of these practices feed on the capitalist market economy, they demonstrate that subsistence production is not limited to rural places or developing countries.

Subsistence Within Capitalism

As in any society, a capitalist market society is built on the production of subsistence. The labor of the workers that capitalism depends on needs to be reproduced as do the lives of the capitalist class itself. For this, subsistence production is necessary, to translate the exchange-value of capital back into use-values. Meals need to be procured and prepared. The young, the ill, and the elderly need to be taken care of. Houses and bodies need to be cleaned. In a capitalist society, subsistence labor is predominately provided by women who receive little recognition and compensation for their work. At the same time, much of the subsistence work has been pressed into commodity arrangements. For example, home-cooking as the main form of food preparation has been increasingly replaced by purchasing ready-made meals. Although both ways may feed a person nutritionally, they are decisively different in their social and cultural implications. Where food is prepared and shared without the exchange of money, mutual social obligations and ties, in short, community is created. Meals prepared reflect the cultural preferences, imagination, and skill of those who cook. Where food is sold as a commodity, however, the social relations between cook and waiting staff (or factory worker and supermarket employees), on the one hand, and consumers, on the other hand, are limited to the market transaction. Meals as commodities reflect the preferences of many and are thus more standardized. The same observation holds for the production of foodstuffs on farms. Since the emergence of industrial agricultural and supraregional trade, the diversity of plants,

plant varieties, and animal breeds on farms has plummeted.

Although subsistence production continues to exist within a capitalist society, this is not a peaceful coexistence. In his description of capital's primitive accumulation beginning in the late fifteenth century, Karl Marx (1977) describes how English peasants got systematically removed from their land to turn the former into dependent wage workers in the emerging industries and the latter into a tradable commodity. In short, this created the conditions for a capitalist economy. Rosa Luxemburg (1968) goes further in arguing that this dispossession of noncapitalist classes was not just a singular precondition, but a permanent requirement to the reproduction of capitalism. While Luxemburg was mainly focusing on Europe's colonies, she also referred to the non-monetary labor of women, a point that later got elaborated in more detail by feminist writers such as Silvia Federici (2004) and Veronika Bennholdt-Thomsen and Maria Mies (Bennholdt-Thomsen and Mies 1999). Federici argues that it was not just the dispossession of peasants and the colonies that laid the foundation for capitalism, but especially the systematic and violent destruction of female power, as exemplified in the witch hunts.

Going on since the emergence of capitalism, the subjugation of subsistence production gained new momentum after World War II, when the victorious powers pushed an agenda of *development* with the aim to modernize every part of the world, shorthand for forcing subsistence producers into industrial modes of production. Walt Rostow (1960) describes development as a natural occurring process, in which traditional (subsistence-oriented) societies were considered undeveloped and immature and had yet to reach the "age of high mass-consumption." Other writers around the same time identified character deficiencies among traditional people that prevented them from reaching higher levels of human development that could be overcome through education and integration in the industrial production processes.

Not only did this mainstream development theory build on a colonial narrative that rendered the indigenous populations of the colonies as lazy and

morally inferior, it is also strongly rooted in a patriarchal tradition. The kinds of activities that are to be promoted through development, including wage labor, financial investing, farming for profit, are activities that were dominated by men; partly because women were excluded from them, partly because many women have other priorities. Consequently, the subsistence work of women was not only made invisible, but their priorities also did not figure equally in development goals and policies and the consequent allotment of resources.

This development ideology became institutionalized in the Marshall Plan and the Bretton Woods program, two development programs led by the United States of America. These programs aimed to provide capital to developing countries to invest in their infrastructure, which would initiate a development similar to the one that the United States had undergone in the previous decades. These development funds were given out under the condition that chemical-intensive export agriculture and industrial development were promoted. At the same time, food aid, heavily subsidized grain commodities from industrialized nations, were exported to developing countries, destroying local networks of provisioning. When developing countries became unable to service their loans, the International Monetary Fund, governments of the industrial countries, and private banks agreed to debt cancellations under the conditions that social services and other government spending were drastically reduced, markets opened to the global economy, and resources privatized (McMichael 2011).

These measures had devastating consequences for rural subsistence farmers. Unable to subsist on the land, millions of rural people moved to urban centers throughout the world, to either work as wage laborers or find themselves unemployed and living in ever-growing slums (McMichael 2011). The similarities with Marx's account of the dispossession of the English peasantry are striking. The age of developmentalism heralded a new round of primitive accumulation, now on a global scale. In many places, subsistence producers rose up against the assault on their traditional livelihoods. In Mexico, for example, an armed conflict

arose in the state of Chiapas between the indigenous Zapatista Army of National Liberation and the Mexican government which had just permitted the privatization of common land as part of Mexico's restructuring program to become fit for the global, capitalist economy.

In the industrialized countries, i.e., countries that already underwent this process of primitive accumulation, the interplay between development and the subjugation of subsistence production took on similar forms. Similar to the developing world, industrial countries invested in the industrialization of their agriculture, i.e., rationalizing the cultivation process so that production was maximized and labor minimized. Governments supported commodity-producing farms with subsidies and publically funded research while more diversified farms based on human labor experienced little support. The shift toward industrial production was enabled through new, expensive technologies and chemicals. This allowed investors to put capital into agriculture like never before. Wanting to see a return on their investments, they favored the production of lucrative commodities while subsistence-oriented farms were largely ignored. Thus, farms that did not qualify for subsidies or credit found it increasingly difficult to compete with bigger, commodity-oriented operations. U.S. Secretary of Agriculture Earl Butz (1971–1976) summarized this policy accurately when he coined the policy “get big or get out.” As a result, almost four million farms (more than half of all farms) in the United States alone got out during the decades following World War II. The picture in Europe was similar.

The farms that persisted were forced to focus more strongly on a few commodities to survive. A double squeeze on agriculture (falling output prices and rising costs for inputs) gave farmers little leeway (Van der Ploeg 2008). Despite being common in the past, fewer farms kept a kitchen garden or a small number of livestock for home-consumption besides their main commodity crops. Standardization and new regulations on food safety made it increasingly difficult to sell small quantities of food products to neighbors. These are farm activities that were traditionally

controlled by women. Consequently, women were made invisible on the farms and their work became increasingly restricted to the household (Veronika Bennholdt-Thomsen and Mies 1999).

Ivan Illich (1982) describes this systematic confinement of subsistence production as capitalism's war against subsistence. Only the destruction of people's ability to provide for themselves makes them so vulnerable that they have to accept the labor conditions set by the owners of the means of production.

In the Eastern Bloc, subsistence-based communities did not fare better. The socialist development as outlined by the historical materialism of Karl Marx saw the peasantry as a reactionary class that had to be turned into (wage-dependent) proletarians, who alone were supposed to be able to lead the revolution. The farming methods had to be industrialized in order to develop the productive forces to the point that they would become too powerful to be contained by a capitalist society. The result was the dispossession of peasant farmers through the collectivization of their land and the industrialization of agriculture, leading to a massive displacement of rural people.

Summary

Food is a central to human subsistence. Besides being a necessity for survival, it is rich in cultural and, for many people, spiritual meaning. In most societies, the ritualized consumption of food is used as an occasion to get together and build social bonds. Subsistence-orientation is the economic preference to put the production of subsistence above financial profit. It has been the dominant motivation for economic activities throughout human history and continues to be the main driver for many people today.

This overview has shown that every human life begins within a pure subsistence economy in the womb of the mother, when the mother unconditionally and involuntarily gives nourishment to the fetus. After birth, the relationship between close relatives, in particular between the mother and child, usually continues to be characterized by

the giving of unaccounted care and food-provisioning. In hunter-gatherer and peasant societies, the orientation toward meeting material, cultural, and spiritual needs is extended to larger social groups, such as the band, the clan, or the village. Even in societies based on wage labor and with a strong division of labor, in which personal ties have largely been replaced with anonymous market transactions, many people cultivate direct, personal relationships within their neighborhood. Often, these relationships are built around shared food. While often portrayed as rural, subsistence-orientation is not foreign to cities. Many forms of urban agriculture are destined to directly feed people with culturally appropriate food. Dumpster divers and garbage gleaners, by choice or not, salvage palatable food waste and distribute it for consumption. And in the city, too, a mother will feed her baby.

Although subsistence-oriented production of food is pervasive, it occurs in an uneasy relationship to the hegemonic capitalist social order. Capitalism depends on subsistence labor (disproportionally expended by women) to secure the reproduction of the labor force, and it also limits autonomous spheres of subsistence production that might subvert the creation of commodities on which the accumulation of capital depends. Thus, the development of capitalism is based on a continued dispossession of the means of subsistence production, which are then reorganized to facilitate the accumulation of capital.

Subsistence-Oriented Farming

► Peasant Farming

Substantial Equivalence

Andrea Borghini

Department of Philosophy, University of Milan, Milan, Italy

Synonyms

[Equivalence of GM; Non-GM foods](#)

Introduction

The expression “substantial equivalence” stands for a key concept introduced to evaluate the risks and the means of production and consumption of novel foods. In particular, the concept has famously been employed to evaluate the risks for human health of consuming genetically modified (GM) foods, that is, of genetically modified organisms raised for human consumption as well as foods that contain these organisms as ingredients (cfr. Andrée 2007; Gupta 2013; Shahin 2007). In a nutshell, that the GM food is substantially equivalent to its non-GM (“natural”; see entry on ► [“Metaphysics of Natural Food”](#)) counterpart is an important reason to regard the GM food as safe to be consumed.

For instance, if a variety of GM corn is substantially equivalent to the non-GM corn variety from which it was engineered, then the GM corn is likely to be considered as safe to be consumed as the non-GM counterpart. Derivatively, and more generally, the *doctrine of substantial equivalence* holds that, from the perspective of human health, GM foods are as safe to be consumed as their non-GM counterparts.

The doctrine has been endorsed by a number of agencies worldwide, starting with the United States Department of Agriculture and the United States Food and Drug Administration; other notable endorsements include the Canadian Food Inspection Agency, the Food and Agriculture Organization of the United Nations, the World Health Organization, and the Organization for Economic Co-operation and Development.

Although the doctrine owes its name and makes reference to two eminently metaphysical concepts, namely, substance and identity, metaphysicians devoted little or no attention to the underpinnings of the doctrine.

The Doctrine of Substantial Equivalence

GM foods constitute a particularly interesting category of *novel foods*. Their novelty, indeed, stems from their different genetic makeup. As the modification of a genome takes place in a laboratory and is thus the product of human intellectual ability and artifice, the resulting novel organism is oftentimes awarded a patent, in recognition of its intellectual specificity. Questions arise, however, regarding the potential threats to human health of the novel food. For instance, it is unclear whether the novel genome will alter the production of the nutrients provided by the food, such as proteins, amino acids, or carbohydrates. It is also unclear whether the novel food will contain vitamins, minerals, potential toxicants (e.g., solanine in potatoes, erucic acid and glucosinolates in canola), and allergenic proteins. Thus, before introducing a novel food into a marketplace, competent food safety agencies need to assess the food's risks to human health. It is at this stage that the doctrine of substantial equivalence finds employment.

To regard a GM food as substantially equivalent to its counterpart, a number of properties of the novel food are examined. If the properties are found to be fundamentally identical to the corresponding properties of the non-GM counterpart, then the food is regarded as safe, from a nutritional point of view. The GM food and its non-GM counterpart are "equivalent," hence, because they are *identical in some key nutritional properties*. They are "substantially" equivalent, instead, because not all of the foods' properties are taken as relevant to justify the equivalence claim: only those properties that are fundamental from a nutritional point of view are salient to determine the matter.

Disagreement has risen among the international scientific community on which properties

shall constitute the basis of comparison between a given GM food and its non-GM counterpart. Typically, the fact that the GM food and its non-GM counterpart have different genomes – fact that is crucial to award a patent to the inventor of the GM food – will be deemed as irrelevant from the point of view of human nutrition and health. Thus, in light of the doctrine of substantial equivalence, it is possible that a GM food is considered a novelty within a country's patent office, but standard within that country's food safety agency.

Upon presenting the doctrine, it is important to clarify its scope. Ascertaining the substantial equivalence of a GM food with respect to its non-GM counterpart is only one part of the process of evaluating whether and how to produce a GM organism and to introduce it in the marketplace. Following the EU regulations circa the production and marketing of GM organisms (see entry on ► ["EU Regulatory Conflicts over GM Food"](#); ► ["GMO Food Labeling"](#)), we may divide up the evaluation of a GM organism in four categories.

Substantial equivalence contributes in different manners to the evaluation of a food in each of the four categories.

- (i) *Biosafety*. Substantial equivalence pertains primarily to the assessment of the *biosafety* of the GM organism. In particular, it concerns the safety of consumers, as opposed to – for instance – the safety of biodiversity within an area of production. The appeal to substantial equivalence has thus served to argue that GM foods raise no distinct threat to human health because they do not deliver novel nutritional constituents to the organism.
- (ii) *Labeling*. Substantial equivalence influences also the practices of food labeling. If a GM food is substantially equivalent to its non-GM counterpart, from a nutritional standpoint there is no reason why the two sorts of foods should be distinctly labeled.
- (iii) *Traceability*. The doctrine of substantial equivalence has arguably jeopardized the possibility of tracing the effects of GM foods on human health. Countries that have endorsed the doctrine, and where GM foods

are not distinctly labeled, have rendered impossible for consumers to study whether the emergence of certain allergies (e.g., food allergies and intolerances) and diseases has been influenced by the consumption of GM foods.

- (iv) *Freedom of choice.* By blurring the distinction between GM organisms and their non-GM counterparts, the doctrine of substantial equivalence has weakened the freedom of producers and consumers to choose what sort of product they wish to, respectively, eat or deliver to the market.

Substantial equivalence has an underlying role also in the 2003–2006 debate within the World Trade Organization on the measures that are necessary to protect human, animal, or plant life or health. The debate eventually led to the so-called SPS Agreement – the Agreement on the Application of the Sanitary and Phytosanitary Measures (see the entry on ► [WTO GMO Dispute: Implications for the SPS Agreement](#)). If GM organisms are deemed as substantially equivalent to their non-GM counterparts, then countries that buy into the SPS Agreement have no reasons pertaining to the safety of human nutrition for impeding production of GM organisms or for distinctly labeling GM foods.

Empirical Evidence Against the Doctrine

The doctrine of substantial equivalence is of dubious scientific rigor. In their seminal 1999 article on the topic, Millstone, Brunner, and Mayer remarked that:

The concept of substantial equivalence has never been properly defined; the degree of difference between a natural food and its GM alternative before its ‘substance’ ceases to be acceptably ‘equivalent’ is not defined anywhere, nor has an exact definition been agreed by legislators. It is exactly this vagueness which makes the concept useful to industry but unacceptable to the consumer. Moreover, the reliance by policymakers on the concept of substantial equivalence acts as a barrier to further research into the possible risks of eating GM foods. (Millstone et al. 1999a, p. 525; cfr. also Millstone et al. 1999b for a sequel)

After nearly 20 years, a good deal of empirical and theoretical evidence against substantial equivalence has been amassed. From a more practical point of view, a first criticism concerns the looseness of the concept of substantial equivalence. Little has been done to tighten it. Rather than being treated on a par with novel chemical compounds such as food additives, pesticides, and pharmaceuticals, GM foods were regarded as safe once a few basic data on their biochemical properties had been provided.

Specific data have recently been collated to show important nutritional differences between GM foods and their non-GM counterparts. In a study of the variation of nutritional values among three sorts of soybeans on the market – GM, non-GM conventionally farmed, and non-GM organically farmed – researchers were able to discriminate “all the individual soy samples . . . into their respective agricultural practice background” (Bøhn et al. 2014, p. 14). Other strategies for the analysis of transgenic foods suggest that, contrary to the prevalent view held so far, even from a nutritional standpoint, non-negligible differences exist between GM foods and their non-GM counterparts (cfr. Valdés et al. 2013). The equivalence, that is, was apparent in that the wrong cluster of properties had been selected. But, there is more to the story, which relates to broader theoretical pre-suppositions within the doctrine of substantial equivalence.

Theoretical Evidence Against the Doctrine

The doctrine of substantial equivalence employs, in an unorthodox fashion, a conceptual tool of Aristotelian descent – the theory of substance. In Aristotelian philosophy, the identity of a substance is defined on the basis of some essential properties, which are selected among a larger cluster of properties, including both essential and accidental ones. Thus, for instance, a human is essentially a rational animal, while accidentally it may be tall or short, sitting or standing, and bold or hairy.

The doctrine of substantial equivalence, however, seems to adopt a double-standard approach to a given food that is questionable. In order for a food to count as both novel (at a patent office) and standard (at a food safety agency), one of the two following views has to be held. Either what is presented to the two offices is not the same entity or, if it's the same entity, one of the two agencies (or both) overlooks some of the food's essential properties. Call the first the *miracle view* (it multiplies entities), while the second the *deflationary view*. Both of them face considerable difficulties.

The deflationary view is suitable to those that take a deflationary attitude regarding governmental procedures of sorting and labeling. This is an attitude that weakens the ontological presumptions of such procedures. For instance, suppose a governmental agency registers a citizen as a Caucasian male. The deflationist will hold that such a classification says little with respect to the real racial profile and sexuality of the citizen. Analogously, suppose a food safety agency claims that a GM food is substantially equivalent to its non-GM counterpart. The deflationist will regard such a claim as saying little real with respect to what the food is. While "Caucasian male" and "substantially equivalent" may partially capture the real identity of a person or a food, their role is to serve a specific practical purpose for a government and its citizens.

The deflationary attitude has two significant drawbacks. First, it promotes a form of skepticism towards food labels. The skepticism runs against those who take food labels seriously. Second, in the debate over the palatability of the doctrine substantial equivalence, the deflationist leaves open a worrisome possibility: that the double standard applied by the patent office and the food safety agency is motivated by practical purposes, which run against the purposes of the citizens, who demand that the label be as close to describing the real food as possible.

The shortcomings of the miracle view, on the other hand, are more obvious: it is in striking contradiction with ordinary talk. The miracle view can be savaged only by suggesting that the judgments of the patent office is not on the *food*, but rather on a specific DNA sequence, while the judgment of the food safety agency pertains to the

food and not to the DNA sequence. While such an analysis may be accurately describing extant practices, at once it points out the lack of a comprehensive and systematic treatment of regulations pertaining to GM foods (cfr. Andrée 2007).

The theoretical tenability of the doctrine of substantial equivalence has been criticized from another significant angle. The claim, in this case, is that the doctrine leaves no room for certain qualitative considerations of the food that are of importance to consumers. As Sylvie Pouteau writes in a classic paper:

The misuse of equivalence points to the fact that food quality cannot be restricted to mere substance and that food acts on human beings not only at the level of nutrition but also through their relationship to environment and society. Besides chemical, toxicological, and immunological issues, ethical issues should also be addressed. Beyond substantial equivalence, "qualitative equivalence" and "ethical equivalence" are to be found as ethical counterparts. (Pouteau 2000, p. 276)

According to Pouteau, the doctrine of substantial equivalence should be replaced by a doctrine of *ethical equivalence* (cfr. Pouteau 2000, 2002; Madsen et al. 2002). What matters to citizens and consumers is that GM foods and their non-GM counterparts are equivalent from an ethical standpoint. Judgments of ethical equivalence will be based not solely on the biochemical properties of the foods, but on additional properties of the foods that are ethically relevant. Pouteau's position has been rounded off by studies that point out the importance of familiarity, risk, and method of production in assessing the equivalence of GM foods and their non-GM counterparts (cfr. Siipi and Launis 2009; Meghani 2009; Gupta 2013).

The suggestion, ultimately, is that governmental agencies should base their respective guidelines regarding the production and marketing of GM foods not simply upon some (disputable) biochemical properties of the foods, but also upon relevant ethical properties. Through appropriate labeling requirements, consumers should be consented to make an informed choice about their diet: a choice that allows tracing back potential sources of allergies, intolerances, and diseases and a choice that reflects the consumer's ethical commitment to a tradition, to a system of production, and to a specific risk-taking conduct.

Summary

According to the doctrine of substantial equivalence, from the perspective of human health, GM foods are as safe to be consumed as their non-GM counterparts. While a number of governmental agencies and institutions worldwide have endorsed the doctrine, important criticisms have been raised against it. After rehearsing the key tenets of the doctrine, the entry surveys its major practical and theoretical shortcomings. From a practical point of view, not only is “substantial equivalence” loosely understood in national and international regulations, but some recent studies point out to some nutritional differences between GM foods and their non-GM counterparts too. The theoretical shortcomings of the doctrine, then, rest on its problematic use of some classic metaphysical concepts (i.e., substance and identity) as well as on its lack of consideration for ethical properties that are of importance to consumers, such as risk, familiarity, tradition, and method of production.

[Health foods](#); [Medicinal foods](#); [Naturally functional foods](#)

Introduction

Superfoods are an increasingly significant category of health foods that are celebrated for their supposed extraordinary nutritional and/or medicinal properties, their histories of traditional use by ancient or indigenous communities, and their “natural” and “authentic” qualities (Loyer 2016). There is no standard definition of the term “superfood”; it is not a legal or regulatory category such as “organic” or “fair trade,” nor is it used by scholarly convention as is the term “functional food” (Lunn 2006). It can be considered a subcategory of the latter because superfoods are marketed for their health benefits and are referred to in the marketing literature as “naturally functional” (Mellentin 2014). The term appears prominently on product packaging, in marketing, and in the media, where tentative scientific findings regarding a food’s healthfulness, often funded by economically interested parties, are frequently exaggerated (Weitkamp and Eidsvaag 2014). While little academic attention has been paid to the category, media stories about superfoods abound; these articles tend to either promote particular superfoods or attempt to “debunk” superfood health claims. However, ethical aspects of producing, promoting, and consuming superfoods are rarely mentioned. Given that these foods are deeply embedded in contemporary global food provisioning networks and nutrition discourse and politics, their production and consumption raise ethical questions regarding their social, environmental, and public health impacts.

Superfoods can be understood both as a popular discourse about food and health and as a group of food products marketed for their “natural” health benefits. As such the category is pulled between critique of contemporary food production, provisioning, and consumption, on the one hand, and commodification of traditional food and culture, on the other. This tension leads to ethical ambivalence in their production, representation, and consumption, as producers and consumers alike attempt to navigate the difficult terrain of what constitutes “good” and “healthy” food, at the same time that these contested qualities are commodified. This entry explores these tensions and the ethical

quandaries they raise by examining superfoods as popular discourse, agricultural outputs, global food commodities, and health food products.

Superfoods Discourse: Between Commodification and Critique

The concept of superfoods is a composite of ideas about food, health, and nutrition and their associated politics, deeply embedded in Western thought and practice. Superfoods have emerged and developed at the intersection of discourses of functional nutritionism, nutritional primitivism, and critical consumption (Loyer 2016). The convergence of these discourses in superfoods forms a critique of contemporary food and nutrition culture, yet this critique is flawed because of the tendency for the values it promotes to become commodified as superfood products are produced, marketed, and sold for profit.

Functional Nutritionism

Superfoods are both a product of and a backlash against the dominant food and health discourse of nutritionism, characterized by “a reductive *focus* on the nutrient composition of foods as the means for understanding their healthfulness, as well as...a reductive *interpretation* of the role of these nutrients in bodily health” (Scrinis 2013: 2, italics from original), often at the expense of other ways of understanding the complex relationship between food and health. Nutritionism not only guides nutritional research and its application but also is deeply embedded in the way that the lay public communicates about food and health: a basic understanding of calories, fats, carbohydrates, and proteins is common knowledge, and in casual conversation, we talk about foods as being low GI, high fiber, nutrient dense, or a good source of omega-3. In recent decades, foods are increasingly represented as vehicles for nutrients, and nutrients are represented as a means of optimizing both general health and specific bodily processes. In this “era of functional nutritionism” (Scrinis, 2013: 4), foods are not only marketed for their health benefits but are also frequently fortified, enriched, or otherwise

altered to improve their nutrient profiles. Superfoods enter this field in a somewhat ambivalent position: they can be considered a type of “functional food” because they are marketed for their nutrient contents and health benefits, but they are also associated with “natural” and “authentic” qualities that formulated functional foods lack.

Nutritional Primitivism

Superfoods also draw upon a discourse of “nutritional primitivism,” defined as “the pursuit of ostensibly simpler, more natural and authentic ways of eating as part of a quest for health through diet” (Knight 2015: 442). Within this discourse, superfoods are desired because they are *not modern*. This places a strong emphasis on foods that have a long history of indigenous culinary and medicinal use, often in remote locations, and thus are seen as traditional and authentic. It also emphasizes foods that are “natural,” that is, perceived as not obviously altered by technology in either the field or the factory and placed in binary opposition to foods produced through blatant technological intervention. These associations provide an alternative way of validating the healthfulness of superfoods through a framework of folk and indigenous wisdom, which suggests that they are healthy not because they have been tested by nutritional science but because they have been safeguarded within traditional and “untainted” food and medicine practices. In this sense, superfoods discourse implicitly critiques both modern food production and nutritional science. Dissatisfied with the medicalization of food and health and the techno-fixes offered by big food manufacturers, those involved in the production-consumption circuits of superfoods look toward the primitive for more intuitive and natural ways of pursuing health through foods. There are two ethical problems with the discourse of nutritional primitivism in regard to superfoods. The first is that there are a range of production practices behind various superfoods, some of which are not particularly “natural” – picture a large monocrop of cranberries, for example. The second is that associating superfoods with “primitive” populations casts remote producers as “Others” who exist in a timeless, imaginary geography, when in reality

they are real people in real places faced with a range of contemporary challenges.

Critical Consumption

A third theme that has acquired significance within superfoods discourse is that of critical consumption, “a way of participating that renders consumption behaviour conscientious and diligent, over a multitude of political and ethical agendas” (Yates 2011: 192). Critical considerations about social welfare and environmental impacts have become an increasingly significant part of the way in which superfoods are produced, represented, and consumed; for example, certifications such as “organic” and “fair trade” frequently appear on product packaging. This theme has become more prominent as superfoods have gained popularity and ever more new, exotic superfood products have appeared on the market. Thus, the discourse has evolved to emphasize not only the healthfulness, naturalness, and authenticity of superfoods but also their socially and environmentally responsible provisioning.

Through the synthesis of discourses of functional nutritionism, nutritional primitivism, and critical consumption, superfoods media and marketing forms a critique of contemporary food and nutrition culture. This critique addresses problems with Western mal- and overnutrition, questions the limitations of nutritional science, indicts a range of modern food production and processing practices, and seeks greater environmental care and social equity. Yet the difficulty with this critique is that it is found prominently on the packaging and websites of companies involved in selling superfood products, who clearly have a strong interest in presenting their products as the obvious solution to the above problems, when indeed other solutions to these problems might be considered, such as growing one’s own food or buying direct from local farmers. Even seemingly neutral superfoods diet and recipe books are often authored by those who seek to profit from selling superfood products – for example, David Wolfe, author of *Superfoods: Food and Medicine of the Future* (2009), owns a company that sells such products, and Julie Morris, author of *Superfood Kitchen* (2012) and other related titles, is the

executive chef for the US superfoods company Navitas Naturals. These potential conflicts of interest, as well as the tendency for values to be co-opted by capital, ultimately make it hard for consumers to trust superfood knowledge claims.

Production: Environmental and Social Impacts

Environmental and Sustainability Concerns

Superfoods are often portrayed as ecologically friendly products, set in opposition to the environmentally destructive practices of industrial food production. For example, in *Superfood Kitchen*, Morris argues that we need ancient superfoods because “efforts to increase food production have resulted in natural food that is less nourishing,” but “most superfoods have not been subjected to this methodology, as they have never been popularized by Big Agriculture” (2012: 14). She encourages her readers to purchase superfoods not only for their own health but also “to send a monetary message to the companies who use chemicals at the expense of public health” (2012: 13). However, this line of reasoning is problematic because it obscures the range of production practices employed across different superfood production-consumption networks, as well as the impacts of increased demand on the ways in which superfoods are produced. Further, it does not sufficiently address the controversial question of the potential environmental impacts caused by transporting products around the world (frequently referred to as “food miles”).

For example, the Peruvian root maca, a popular superfood celebrated for its high nutrient density and supposed fertility supporting properties, is often labeled “certified organic,” yet this does not absolve its production from all environmental impacts. As demand has increased for this central Andean root vegetable, some growers have begun to practice shorter fallow periods, leading to increased soil degradation and the need to use fertilizers. Increased demand has also lead many growers to expand production beyond those regions

historically used for its cultivation, impacting on the grazing range of vicuñas, a native camelid. Local residents of these areas claim that the skittish animals display signs of stress, such as hair loss, which they attribute to the increased presence of noisy tractors and trucks in the region as well as a change in diet as the animals nibble the maca leaves (Loyer 2016). Further, the maca boom has led to several international biopiracy cases, including the controversial filing of patents for maca extracts and pharmaceutical usages by some renowned organizations, and the illegal importation of unprocessed maca root and seed into China, where it is currently being grown and presents a threat to Peruvian intellectual property and market share (Hermann and Bernet 2009; Neuman 2014).

Social Impacts

Increased demand for superfoods also has social impacts on producer communities beyond those addressed through fair trade certifications. The most famous example in this regard is *quinoa* in Bolivia. As demand for *quinoa* has increased, so has its economic value, resulting in the paradox of providing land-based livelihoods for farming communities and repopulating rural regions while simultaneously pricing it out of reach for many of its traditional consumers. Increased demand has also led to community tensions between long-term rural residents and recent returning migrants seeking to profit from the *quinoa* boom, controversial “land grabs” of formerly communal land, and even violent conflicts as potential growers argue over the ownership of prime production land. As with maca, the growing international demand for *quinoa* has led to the expansion of its cultivation outside of traditional areas, decreased fallow periods, increased use of pesticides, and, in turn, soil degradation. The shift of production practices to include tractors and favor relatively flat land has also disrupted the ancient symbiosis between humans, *quinoa*, and llamas, who not only provided meat and wool but also fertilized the land upon which *quinoa* was then grown. This “rupture in the ‘*quinoa*-camelid complex’” has disturbed an ancient and delicate

“ecological balance between crops and animals” (Kerssen 2015: 496).

Marketing: “Othering” and Health Claims

Representing the Other

Associations with ancient or indigenous cultures are a key part of superfoods discourse and feature heavily in marketing and media accounts. Many superfoods are marketed as healthy or even medicinal based on their histories of traditional use by particular indigenous populations, often situated in remote or “exotic” locales such as the Amazon. Examples include the following:

- Açaí, used by the Caboclo population of Brazil.
- Camu camu, used by the Mazamari people of Peru.
- Maca root, domesticated by the Pumpish people of the central Andes but often associated with the legendary Inca.
- Goji berries, associated with the romantic Himalayas.
- Chia seeds, an Aztec staple that became marginalized under Spanish colonial rule.
- Most recently, gubinge or Kakadu plum, a native “bush food” harvested by indigenous peoples such as the Nyul Nyul of northwestern Australia.

Marketing materials and product packaging often employ primitivist discourse and imagery that depicts superfood production taking place in idealized exotic locales by timeless native people. The packaging of popular Australian superfood brand Power Super Foods provides a good example (Loyer 2016). Their maca powder is sold in plastic packages featuring a stylized image of indigenous women, dressed in colorful traditional Andean costumes including identical skirts, shawls, felt hats, and black braids, plucking round vegetables from the earth by hand and placing them into woven baskets as they work against a backdrop of snow-capped peaks and bright blue sky dotted with fluffy clouds. Text declaring maca to be “the Inca superfood”

contributes to this primitivist representation by linking it to the Inca, when it was, in fact, the lesser-known Pumpish who domesticated the root. This representation differs in several ways from observations of maca production practices. Maca harvest workers are not only women; men and children also engage in this work. Harvesters are more likely to be dressed in contemporary clothing, such as jeans and sweaters, than in traditional dress. Maca is not placed into woven baskets, but collected in large plastic sacks. It is not picked by hand, but with the aid of small hand tools, and modern machinery, such as tractors that turn over the soil, is frequently employed, as is modern agricultural science oriented toward increasing efficiency. Finally, the landscape, while striking, is not always so idyllic, and harvesters frequently labor on steep mountainsides at dizzying altitudes above 4,000 m in extremely cold, wet, and windy conditions. The problem with such primitivist representations is the way in which they depict maca production as a timeless practice done by a timeless people. By casting maca production and the people involved in this process outside of intersubjective time and space, they are rendered as imaginary “Others” in the mind of the consumer, instead of recognizing that these are real people who exist in the contemporary real world and must contend with forces of colonialism, cultural imperialism, economic survival, and the influence of global flows (Loyer 2016).

Health Claims

Another ethical problem with superfood marketing is the use of health claims. The use of the term “superfood” on product packaging or in marketing is not regulated in the United States or Australia, but it has been banned in the European Union since 2007 under Regulation (EC) 1924/2006. Certain types of health benefit claims and nutrient content claims are allowed in the United States, Australia, and other countries including Japan, and some superfood products make use of such claims (Heasman 2008; Williams and Gosh 2008). However, a number of potential problems exist with the use of both formal, regulated health claims and vague,

informal claims such as the use of the superfood label. Such claims may place disproportionate emphasis on the consumption of particular foods or nutrients at the expense of an overall healthy diet including a variety of foods and nutrients. They may also lead consumers to expect results from a particular food that are unrealistic. Another problem is the question of dosage: how much of a particular food does a consumer have to eat, and how often, in order to receive a health benefit? This information is frequently excluded in superfood marketing, media, and product packaging.

Consumption: Ambiguity, Equity, and Access

Both superfood products and the discursive concept of superfoods reach Western consumers loaded with knowledge claims regarding their healthfulness, authenticity, and production practices. Superfoods are often positioned as ambiguously straddling the categories of food and medicine and thus may confuse consumers regarding just what a food with such a label promises. In blurring the cultural boundaries between food and medicine, superfoods present many conundrums to consumers, such as what constitutes an appropriate “dosage” and the frequency of consumption required to actually achieve a health benefit. Many superfoods were traditionally consumed as daily staples in their regions of historical consumption, while new consumers may consume them haphazardly and therefore not see measurable results. Further, superfood products are often relatively expensive, which may limit their frequency of use among Western consumers. The high price point also raises the question of access, which is particularly pertinent in an age when wealth disparities are increasingly associated with health disparities.

Further questions of equity and access arise as superfoods gain popularity worldwide and often become economically unattainable for traditional consumers, as previously noted in the case of *quinoa*. There is a paradox here, whereby wealthy Western consumers fetishize superfood products

because of their associations with “healthy” indigenous people not beset by the diseases of excess that haunt contemporary Western food and nutrition culture, while many of the (largely) indigenous people who produce these foods increasingly consume less and less of them because they are either financially inaccessible or culturally scorned in favor of more fashionable “Western” foods such as pizza, fried chicken, and heavily processed snack foods. It may seem easy to place the blame for this paradox on Western consumers, but it is important to remember that many of these products have arrived on the global market as a result of neoliberal economic development and trade programs and policies that encourage developing countries to export distinctive products rather than to develop strong local economies, thus undermining efforts that support food security and food sovereignty in such regions (Crabtree 2002). One alternative to the export of such products is the development of superfood crops in the new consuming countries, such as chia seed which is now an important agricultural product in Australia. However, this raises the ethical issue of whether such international cultivation projects violate the intellectual property rights of the traditional producers and consumers of these foods.

Conclusion

Some superfoods may, indeed, offer superior nutritional and perhaps even medicinal benefits to global consumers. However, in the current market-driven scenario, it remains hard for consumers to differentiate between those products relying on overblown claims backed by limited (and perhaps even biased) scientific studies and primitivist representations and those that may genuinely improve consumer health. Further, serious questions remain regarding the environmental and social impacts of superfood production and consumption and whether such products reinforce notions of cultural difference and patterns of global inequality. Additionally, the emphasis on the production of distinctive products for export in the developing world may negatively affect food

security and food sovereignty efforts. Finally, the move toward specialized superfoods, functional foods, and other supplements in an age fixated by nutritionism and characterized by the individualization of diet, health, and medicine presents a public health challenge in terms of communicating concepts of holistic health.

Introduction

The sustainability of current global agricultural practices is an ethical issue that is attracting greater public awareness. There is increased societal concern regarding the crucial harmonic balance between feeding an ever-growing human population and minimizing environmental damage for the planet's future inhabitants (Broom 2010). Sustainability refers to the long-term success of a system. In order to keep animal agriculture sustainable, changes must be implemented to allow animal production to continue in an efficient and environmentally conscious manner. Such strategies should assess the potential benefits and consequences for all stakeholders involved. These considerations will help to ensure the viability of animal agricultural systems in the years to come.

The overall sustainability of animal production reflects the collective viability of a variety of agricultural aspects including animal welfare, food quality, the environment, and human health. Ethical concerns pertaining to the quality of life for the animals arise from the visible suffering and unnatural behaviors exhibited in intensive farming conditions. Food quality and safety considerations associated with certain agricultural practices have resulted in decreased consumption of animal products by the general public. The concept that a healthy environment is a vital aspect of sustainability has become significantly

more widespread, and a larger population of consumers is beginning to demand responsible practices that minimize contamination and preserve the quality of the earth, water, and air. A scientifically established correlation between the consumption of certain animal products and public health has garnered more attention as chronic metabolic problems, such as diabetes or cardiovascular disease, threaten the public ideal of reaching old age in a healthy state.

With these concerns, comes the need for change. In order to maintain a sustainable system, the animal agriculture industry must first reflect on its responsibilities owed to the public, as well as its negative effects exerted on the environment. Modifications in the use of both new and existing resources should be continually reevaluated in an effort to limit the impact of the industry on the planet and its foreseeable future.

Sustainable Animal Agriculture

Sustainable animal agriculture must address important issues in the production, marketing, and consumption of livestock, poultry, and fish. The concept of sustainability refers to the pressing need to feed a growing human population without damaging the environment beyond repair for future generations, while doing so in a manner that guarantees both functional and moral long-term acceptance (Broom 2010). An animal production system is sustainable if it can be continued successfully in its current form without the need for future modification. A system becomes unsustainable once it begins to use methods that are environmentally, economically, socially, or ethically unviable.

Historically, the use of animals for food complemented the harvesting of crops in ways that added value to plant agriculture and improved the continuous supply of protein for humans. Harvesting of plants is a seasonal event, and thus it presented difficulties associated with the storage of produce prior to modern preservation techniques. The use of animals was advantageous because animals could be harvested over extended periods of time in contrast to plants. Grazing

animals, which consume available vegetation, were essentially viewed as storage units of plant nutrients that could be collected by humans at a later time. The possibility of hunting animals was seen as a strategy to supplement both plant and animal agriculture. The year-round availability of animals to hunt presented a more promising supply of protein and nutrients throughout all seasons. With the arrival of animal agriculture, humans no longer depended exclusively on the animals they hunted. Adequate protein sources could also be provided to society beyond the narrow window of harvest season by storing milk from sheep, goats, and cattle as cheese or yogurts and preparing fish and livestock meat as dried or salted.

Animals have been used to convert plant products unfit for humans into desirable food products, thus broadening the use of plant material and prolonging the availability of food. Ruminants eat grasses and parts of plants such as stalks and shells and can utilize spoiled plant materials that otherwise are not suitable for human consumption. The extension of food availability throughout the different seasons via animal intermediates, along with the primitive desire for animal products, created added value to plant agriculture. Animals have also been used for purposes other than food, such as providing power for work and transportation. Animal skins and fibers have been used for clothing and shelter. Due to the aforementioned reasons, animal agriculture has been market driven ever since its initial establishment during early civilization.

In modern times, concern about the sustainability of animal agriculture in developed countries has increased as animal production systems have transitioned from extensive to intensive systems. Driven by market forces, competition, regulation, and economic subsidies, the intensification of animal agriculture has resulted in the more efficient consolidation of production systems over the last century. Subsequent cost reductions have made the availability of abundant and cheap food of animal origin possible. Increased productivity, however, has not come without a price, and oftentimes, the animals' interests are hampered. In the majority of cases, it is the

animals that are forced to carry most of the burden, which results in a decreased quality of life for animals and the subsequent increased ethical concerns of humans.

Small farms typically have multiple crops and livestock types integrated into production and harvest systems that maintain income over seasons by utilizing natural and seasonal resources. Historically, small farms have remained pasture based or have relied on local sources of feed for livestock, which has limited the livestock density in an area to the carrying capacity of the local environment. Large farms often produce one or two crops and a single type of animal and have competitive advantage in commodity food production through the economic strategies of scale and more efficient use of capital. By sourcing feed from outside the region, large farms can accommodate more animals but consequentially produce more manure than the local environment can handle without strict environmental regulations. The consolidation of farms has occurred in response to decreased marginal profitability in commodity food production, increased consumer demand due to population growth, and heightened public awareness about food quality and safety.

Issues regarding the sustainability of contemporary intensive animal agriculture have been brought to light because the management of animals and animal waste in large-scale animal farming conflicts with the values and ethics of certain sectors of society. While animal production may still add economic value to crops, like corn and soybeans, the historical need to maintain protein in the human food supply over different seasons via the use of animals as intermediates is now a lesser concern due to the development of enhanced long-term storage techniques for grains and other plant protein sources. Recent improvements in the storage of healthy and nutritious foods have resulted in an increased ability to transport food products globally. While upgrades have been made, such systems are not flawless and inadequate storage continues to contribute to resource wastefulness. Approximately one third of the food produced around the world is never consumed because it is instead spoiled or

destroyed by pests during transport (Gustavsson et al. 2011).

Concentrated housing of large numbers of animals burdens local environments and can exceed the buffering capacity of ecosystems to utilize nutrients from manure and control pathogens. While fecal matter from a relatively small number of animals can be absorbed into a local ecosystem, feces and urine from a large number of animals can result in local environmental damage and runoff to surrounding ecosystems. Concentrated animal housing can also promote an increased pathogen load of both animal and zoonotic pathogens, which results in potential health hazards to humans and other animals.

The primary challenges regarding the sustainability of contemporary intensive animal production systems are concerns in the areas of animal welfare, environmental conservation, and resource competition.

Sustainable Animal Agriculture and Animal Welfare

Each animal species has its own biological limitations and needs. If pushed beyond certain physiological limits, animals will start to suffer. Dairy cows, selected for high milk yields and fed a high-energy diet to meet the demands of production, experience decreased immune function and decreased metabolizable energy, which leads to the increased presence of health problems such as mastitis, lameness, and infertility. Sows are social animals and, in natural conditions, live in stable sow groups. When housed in solitary gestation crates, the ability to engage in natural social behavior is prevented. This negatively impacts a sow's emotional state, causing frustration. A manifestation of such frustration is the development of stereotypies, such as bar biting or weaving, which are repetitive obsessive behaviors that serve no clear purpose. The housing of laying hens in tightly confined battery cages inhibits the expression of natural behaviors, like nest building or dust bathing, and can actually lead to the development of unwanted behaviors such as feather pecking or cannibalism. The presence of any of

these examples suggests a decreased quality of life for the animals.

Increasing public concerns about animal welfare and the care of captive animals, particularly agricultural species, affects whether or not the use of animals for these purposes is considered sustainable (Broom 2010). A rise in productivity over the last 50 years has occurred hand in hand with a decreased quality of life for farm animals and an increased societal awareness of industrial farming systems (Harrison 1964). Certain husbandry practices, such as gestation crates or battery cages, are becoming more unacceptable to consumers. As a result, these farming methods become unsustainable, forcing the agricultural industry to modify current systems in order to adapt to consumer demands.

In a market-driven economy, public opposition to the consumption of a certain product diminishes the market success of that particular product. Consumer surveys completed in recent years have demonstrated that the general public is willing to pay more and change traditional shopping habits in order to specifically purchase animal products manufactured using animal welfare conscious practices (Special Eurobarometer 2007). Recent reports indicate that animal welfare concerns extend beyond consumer intent to change shopping habits and have actually resulted in decreased demand for certain foods such as poultry and pork products (Tonsor and Olynk 2011).

The proliferation of faux-meat products over the last few years has presented an additional threat to animal agriculture. These meat analogs use plant proteins to create animal-free products that look and taste similar to meat. With the existing uneasiness about current production standards, the availability of these imitation meat products may create a shift in market trends and further impact the sustainability of certain practices and the future of animal agriculture.

Sustainability of Food Quality and Safety

In addition to animal care and well-being, consumers have expressed concerns about food quality and safety. Decline in the consumption of food

goods believed to be unhealthy or unsafe has caused certain products to become less sustainable. An example of this is the outbreak of bovine spongiform encephalopathy in 1980s, which resulted in decreased beef consumption in Germany and other European countries (Becker et al. 2000). If a certain practice or system is deemed unacceptable, consumers will boycott the purchase of items produced by such means, consequently limiting the viability of a given farming system. Legislation and food vendor standards for farm animal care directly reflect the impact of consumer concerns regarding acceptable food quality and safety. Dismissing and neglecting to address such concerns can have a detrimental effect on a particular sector of the agricultural industry, making it unsustainable.

In market-driven economies of democratic societies, sustainable animal products are those that are manufactured in a manner consistent with consumer acceptance rather than science-based facts and findings. Public perception of agricultural practices, whether accurate or not, determines what standards are considered adequate, and thus, sustainable products are those that are produced in line with the morals, values, and ethics of the consumers who purchase them.

Sustainability of Environmental Impact

Increasing public interest in environmental ethics has popularized the idea that animal agriculture should have a minimal impact on climate and the environment while still providing for the basic needs of the animals. As a whole, the public remains generally accepting of the use of animals for food, but the overall consensus is that production should meet certain standards of both food safety and animal welfare.

The negative impacts that many agricultural practices have on the environment and wildlife contribute to societal uneasiness. Increased production of greenhouse gases, soil erosion, and contamination of waterways are examples of detrimental outcomes that the general public may find troubling and ethically difficult to accept (Tilman 1998).

There is increasing discussion about sustainable balance – a harmonic interaction between animals, caretakers, producers, consumers, general public, and the environment. While such a balance is ideal, it may prove challenging to accomplish in some locations. For instance, it would not be sustainable to raise large numbers of farm animals near highly populated areas due to the competition associated with the coexistence of both populations in relatively close quarters (McGlone 2001).

Biodiversity is an important conservational tool, and the presence of monocultures can result in catastrophic disease outbreaks and adverse environmental conditions. When acres of land are dedicated to a limited number of species, problems more frequently result in damage that is difficult to repair. Similarly, the concentration of a limited variety of farm animal species in a single geographic region may increase the potential for disease transmission as well as other management problems. These outcomes can have a devastating impact on the agricultural industry and its sustainability.

Excessive use of fertilizers and management of manure associated with large-scale production have lead to exacerbated nitrogen and phosphorus contamination of the environment in certain parts of the world (Foley et al. 2011). Contamination of the underground water table with these waste products has long-term consequences that are not sustainable for the environment. There are also documented concerns about the presence of genetically modified organisms in food products (Burton et al. 2001). Regardless of whether or not this uneasiness is based on scientific evidence related to product safety, it still possesses the ability to make a particular production model undesirable to the public.

A stressful environment impairs immune function, and thus, providing less stressful farming conditions for animals can indirectly prevent pathogen proliferation (Rostagno 2009). Humane husbandry and treatment help lessen the risk of both disease development and spread through a farm. Not only do humane practices address ethical concerns regarding the well-being of farm animals but are also important to ensuring public safety.

Many animal pathogens such as *Salmonella* spp. and *Escherichia coli* O157:H7 are zoonotic. Even on farms where antibiotics are not routinely administered, enhanced biosecurity measures can help control the levels of such microorganisms and subsequently reduce the likelihood of transmission to humans.

The expansion of agriculture over the last few decades has resulted in an increase in greenhouse gas emissions (Foley et al. 2011). Greenhouse gases in the atmosphere help maintain the surface temperature on earth by acting like a blanket that traps warm air close to the surface. This form of environmental temperature regulation is essential for all life on the planet. As concentrations of greenhouse gases increase, more solar radiation becomes trapped within the blanket of gases causing temperatures to rise. This results in global warming, which has been documented to adversely affect environmental living conditions (Intergovernmental Panel on Climate Change 2007). There is a definitive need to reduce greenhouse gas emissions (United Nations 1998). Agriculture as a whole is responsible for over 30% of global greenhouse gas emissions, and livestock farming alone accounts for 18% of such emissions (Food and Agricultural Organization 2006). Considering the impact of greenhouse gases on global warming, it is clear that current practices of animal agriculture are both environmentally and ethically unsustainable.

Energy is lost in the form of heat when animals convert protein from vegetables to meat or other forms of animal protein, which is an inefficient use of resources (McMichael and Butler 2010). Development of land to grow corn or other grains, which can be directly and adequately consumed by humans, is not sustainable when such crops are instead used to feed animals. Simply put, there is a two-step process that must take place in which (1) animals eat the crops and (2) humans eat the animals. The addition of a “middle man,” which in this case is the animal, creates another outlet for energy loss when instead those plant resources could be utilized directly and more efficiently by humans.

Swine and poultry are food animals that may be considered less sustainable from a production

standpoint. These animals act more in direct competition with humans when it comes to plant energy because neither species contains a specialized digestive system that allows for the breakdown of unique plant material. Alternately, ruminants graze pastures or browse bushes that cannot be directly utilized by humans. While ruminants play a minor role in the release of methane, carbon dioxide, and other greenhouse gases (via eructation), the fact that humans and ruminants do not use the same energy sources makes the production of these animals a more sustainable practice (Murgueitio et al. 2011). In this context, animal agriculture allows plants to be metabolized by humans (Bradford 1999).

Sustainability of Public Health

Population expansion brings with it an increased demand for food and water. A rise in meat consumption occurs in areas of sustained economic growth. The shift from plant to animal protein that occurs as countries develop is referred to as a *nutrition transition* (Popkin 2003). This transition does not come without consequences, as human health is affected by excess consumption of saturated fats of animal origin. The American Heart Association currently recommends a daily amount of less than 6 oz of meat, including fish and chicken (American Heart Association 2013), when in reality, average intake is much higher. Significant levels of saturated fats acquired through meat consumption have been linked to the development of chronic health problems like obesity, cardiovascular disease, and diabetes (World Health Organization 2003).

Increased public awareness has resulted in greater concerns involving the possible contamination of animal products with antibiotics and hormones that are routinely administered to most farm animals for nontherapeutic reasons. Consumers may begin to rely on nonanimal sources of protein in order to avoid the potential health risks associated with the consumption of foods contaminated with such chemicals. There may also be a trend shift in what consumers find acceptable from a health standpoint. An example

is the possibility of using more natural feed additives, from chicken manure to restaurant waste, instead of chemicals, antibiotics, or hormones.

Summary

Changing societal values are forcing those involved in animal agriculture to reassess certain practices that have become standard over the last few decades. Intensification of animal production has resulted in increased public awareness regarding the ethics of such practices and the potential effects on the environment, animal welfare, food quality, and human health. The long-term sustainability of animal agriculture relies on the industry's ability to respond to consumer concerns and maintain practices that are socially, economically, and environmentally sound.

Introduction

The modern use of the concept of sustainable development refers to management of the use of natural resources aimed at balancing availability of natural resources with consumption with a view to promote economic growth and social well-being. Sustainable development has played a central role in international governance of food production and consumption throughout the last 25 years. The concept of sustainable development is implemented in two international governance frameworks: the Convention on Biological Diversity (CBD) and the United Nations Framework Convention on Climate Change (UNFCCC).

The scope of this entry is to examine the concept of sustainability and sustainable development and its role in governance and policy of food production and consumption. Section “[Sustainable Development as an Ethical Ideal in International Policy](#)” examines the concept of sustainable development as an ethical ideal and how different environmental ethics approaches together with cultural and political values influence the task of determining the focus of a sustainable development and how it should be obtained; section “[Three Dimensions of Sustainability: The Convention on Biological Diversity](#)” examines the complex interrelation between economic, social, and environmental sustainability in food production in light of the governance

principles for sustainability outlined in the CBD and its protocols. Section “[Climate Change as a Challenge to Sustainable Development of Food Production and Consumption](#)” addresses the challenges of climate change to sustainability in food production and consumption and examines these in light of the objectives of adaptation and mitigation set out in the UNFCCC and the Kyoto Protocol; different governance approaches with view to promote climate sustainability in food production and consumption including the concept of food miles and carbon footprint are discussed. The entry concludes with a suggestion of some key principles for governance of importance to sustainability in food production and consumption in the future.

Sustainable Development as an Ethical Ideal in International Policy

The term sustainability, as it is used today, has its origin in the outline of sustainability in *Limits to Growth*, a report for the Club of Rome’s project on the Predicament of Mankind from 1972 where sustainability is described as “a world system that is: (1) sustainable without sudden and uncontrolled collapse; and (2) capable of satisfying the basic material requirements of all of its people” (Meadows et al. 1972, p. 158). While the industrialization of agricultural and livestock production in the 1960s brought tremendous economic growth, the negative impacts on the environment and their long-term consequences for social and economic development became a growing concern among scientists, philosophers, and policy makers during the 1970s and 1980s.

In 1987 the United Nations World Commission on Environment and Development published the report “Our Common Future” (the Brundtland Report). The report examines the relation between societal development and degradation of species and genetic resources. The Brundtland Report argued in favor of a “sustainable development,” which was defined as a development which seeks to meet the needs and aspirations of the present without compromising the ability to meet those of

the future (World Commission on Environment and Development 1987, p. 84).

The Brundtland Report laid the ground for the adoption of Agenda 21 at the Earth Summit on environment and development held in Rio in 1992. Agenda 21 (<http://www.un.org/esa/dsd/agenda21/>) is an international agreement of actions to achieve sustainable development. The Rio Earth Summit also led to adoption of the Rio Declaration on environment and development (http://www.unesco.org/education/information/nfsunesco/pdf/RIO_E.PDF).

Furthermore, the CBD was opened for signature during the Rio meeting, and the UNFCCC was agreed. Both conventions play an important role aiming at environmental sustainability in food production and consumption with a view to ensure economic growth and promote social well-being.

The Brundtland Report's definition of sustainability/sustainable development plays a central role in these frameworks. The concept can best be described as an ethical ideal concerned with the ethical relation (a) between humans and non-human nature and (b) between present and future generations. The ethical motivation behind the concept of sustainable development reflected in the Brundtland Report echoes an anthropocentric-oriented ethical approach to environmental protection. The idea of sustainable development is based on the common interest of humankind to protect nonhuman nature as the foundation for our human existence and well-being (World Commission on Environment and Development 1987, pp. 71–86). The concept of sustainable development reflects the idea of inter-generational justice; it advocates an ethical responsibility of present generations to ensure that their pursuit of economic and social development, does not compromise the possibility for future generations to meet their needs and aspirations. However, the motivation for establishing sustainability and determining what sustainable development should entail depends on the cultural, ethical, and political values embedded in different worldviews or perceptions of the relationship between humans and nonhuman nature. Environmental value-based ethics approaches such as biocentrism or

ecocentrism represent an alternative to the anthropocentric approach. According to these approaches life and/or ecosystems as a whole represent an autonomous intrinsic value which human beings ought to respect in and by itself (Rolston 2012, pp. 110, 116). Thus, a biocentric or an ecocentric approach may be less prone to accept trade-offs in terms of compromising protection of biodiversity or specific habitats or endangered species for the sake of promoting social and economic sustainability, for example.

Determining Sustainability: Implications of Cultural, Ethical, and Political Values

The concept of “sustainable development” as it applies to governance of food production and consumption has three dimensions: an economic, a social, and an environmental dimension (World Commission on Environment and Development 1987, pp. 174–175). These three dimensions are likely to conflict. Ideally sustainable development is to take into account all three dimensions, without compromising one over the other. In reality, however, initiatives to establish sustainability in one dimension may involve trade-offs in another. For example, food production may be sustainable in terms of providing enough food and ensuring distribution so to avoid food shortage in vulnerable regions of the world, but it may not be environmentally sustainable. Similarly there may be trade-offs within the same dimension of the concept. For example, it is not difficult to imagine that a production method can be sustainable in terms of protecting specific aspects of biological diversity, but not in terms of the energy output and contribution to anthropogenic climate change.

Determining what is required to establish sustainable development in a specific context and the acceptance of trade-offs does not only depend on the primary objective of sustainability, i.e., whether the goal is to establish climate sustainability or social sustainability, but also on the cultural and ethical values of the various stakeholders.

Likewise, political values and beliefs play an important role for determining what governance

instruments are necessary to establish sustainable development. At least three major governance approaches to sustainability are reflected in international policy on food production and consumption: (1) a neoliberal approach to sustainable development in food production and consumption argues that market mechanisms can ensure sustainability because an increase in price of scarce resources is likely to encourage more efficient use or use of alternative resources. (2) A conservationist approach emphasizes the necessity of living in accordance with the natural environment, respecting the limits that is set for human activity and for economic growth. A sustainable use of resources for food production in this context would include careful management of existing resources including development of environmentally friendly agricultural methods, focusing on promoting small-scale and local farming. High-tech or large-scale farm industry approaches to solve problems of food security or environmental problems are usually not associated with sustainability in this context. (3) An institutional approach emphasizes the importance of environmental protection through changes in both production and consumption patterns encouraged, for example, by market-based instruments introduced by governments. Changes in production and consumption patterns have to happen through institutional changes, which could involve regulation of multinational companies, or introduction of taxes that may push production and consumption in more eco-friendly and environmentally sustainable directions (Oosterveer and Sonnenfeld 2012, pp. 41–44).

Over the years the concept of sustainability and sustainable development has been criticized for being vague. However, it must be emphasized that the way the concept is implemented in the two key international governance frameworks for sustainability in food production and consumption, the CBD and UNFCCC, represents an ethical ideal, which frames international policy and requires interpretation. Ethical and political debate about sustainability including debate on governance approaches and specific strategies is crucial in order to balance actions according to different values and economic, social, and

environmental interests. The interrelatedness of these three dimensions of sustainability together with the complex challenge they represent to the objective of sustainability in food production and consumption is examined in the following Section.

Three Dimensions of Sustainability: The Convention on Biological Diversity

The development of the CBD began in 1987 and was an attempt to harmonize existing conventions with relevance to biodiversity. The convention came into force on 29 December 1993 and now has 193 parties according to its official website (<http://www.cbd.int/>). Today the CBD is the main international instrument addressing issues related to conservation of biological diversity. The CBD has three major objectives: conservation of biological diversity, sustainable use of biological diversity, and fair and equitable sharing of benefits from its utilization. It was established with the aim to protect global biological diversity, recognizing that natural resources necessary for economic development are not unlimited (Secretariat of the Convention on Biological Diversity 2005, Sect. 1, CBD Preamble). A number of thematic work programs are established under the convention to promote conservation and sustainable use of biological diversity in specific areas including marine and coastal areas, agriculture, forests, inland waters, and dry and subhumid lands (Secretariat of the Convention on Biological Diversity 2005, p. xxx).

The convention reflects a holistic approach to sustainability, where a sustainable use of natural resources can be summarized as one that takes into account the need for economic and social development through production and consumption without jeopardizing the value of biological diversity (Secretariat of the Convention on Biological Diversity 2005, Sect. 1, CBD, Article 1). The motivation for establishing sustainability is the recognition of the value of biological diversity, which is referred to as both an intrinsic value and a multifaceted value that includes the ecological, social genetic, economic, scientific,

educational, cultural, recreational, and aesthetic value that the diversity may represent to a nation, to a society, or to the individual. The convention reflects a perception of biological diversity as a collective good which is of “common concern of humankind” (Secretariat of the Convention on Biological 2005, Sect. 1, CBD Preamble). To protect this collective good, the convention sets out egalitarian governance principles for protection of biological diversity while not jeopardizing the objectives of socioeconomic sustainability. Efforts to protect biological diversity and ensure sustainable use of genetic resources are to be carried out according to principles of justice emphasizing the need for socioeconomic sustainability through a fair and equal distribution of resources and sharing of benefits and costs related to protection and use of biological diversity as part of the effort to ensure human well-being through social and economic development (Schroeder and Pisupati 2010, p. 5).

Two protocols have been added to the CBD since 1993: the *Cartagena Protocol on Biosafety* (adopted in 2000) and the *Nagoya Protocol on Access to Genetic Resources and the Fair and Equitable Sharing of Benefits Arising From Their Utilization to the Convention on Biological Diversity* (adopted in 2011) (Secretariat of the Convention on Biological Diversity 2000, 2011).

Both protocols illustrate the complex challenge of balancing the environmental, social, and economic dimensions of sustainability in food production and consumption.

Economic Development and Environmental Sustainability: The Cartagena Protocol

The central policy objective of the Cartagena Protocol (2000) is to establish a balance between the interests in exploiting modern biotechnology as a means to economic development, with the potential environmental and social impact in terms of negative risk to human health and the environment. This policy is based on the precautionary principle, which is outlined in the Rio Declaration's principle 15 which states that

Where there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-efficient

measures to prevent environmental damage (http://www.unesco.org/education/information/nfsunesco/pdf/RIO_E.PDF).

The Cartagena Protocol sets out criteria for risk assessment of the environmental impact of new biotechnologies for use in food production, in agriculture, and in healthcare where there are potential adverse effects to human health and the environment (Secretariat of the Convention on Biological Diversity 2000, pp. 1–2).

The Cartagena Protocol is also concerned with the socioeconomic impact of establishing biosafety. Distributive justice and justice in the exchange of knowledge and research play an important role in this context. The principles of fairness and equality are promoted both with respect to the distribution of benefits from biotechnology to human health or to agricultural production among the parties of the convention and with respect to the sharing of research and know-how of importance for the establishment of the necessary precautionary measures that allows for safe use, for example, application of genetically modified (GM) crops for food and feed should include appropriate assessment of risk to human health and to the environment in local communities.

When GM crops were first introduced in the 1990s, they were promoted by large multinational companies, as a potential solution to problems of food security. Nevertheless, application of GM crops in food production has been met with skepticism among consumers in many countries and especially in the countries of the European Union, where the lack of obvious consumer benefits and biosafety concerns has been the main reason for rejection of GM crops for food production (Gaskell et al. 2006). Among the major critiques are that GM crops, due to the fact that these are primarily produced by large multinational companies who protect their economic interests through patents, contribute to socioeconomic disparity and to an unsustainable development in food production altogether. However, scenarios outlined among others in the Intergovernmental Panel on Climate Change (IPCC), working group II's report from 2007 assessing *The Impacts, Adaptation and Vulnerability including the impact of*

climate change on *Food, Fibre and Forest Products* (Easterling et al. 2007, pp. 275–303), have given rise to renewed debate on the potential benefits of GMOs to the aim of food security and environmentally sustainable food production.

The necessity of policy actions to promote justice in distribution and exchange of research and technology including new ways of approaching the problem of patenting and intellectual property rights in relation to development of GM crops has been mentioned as crucial for the establishment of sustainability with respect to food production and environmental protection (The Royal Society 2009, pp. 45, 50).

Environmental Protection and Economic and Social Sustainability: The Nagoya Protocol

The Nagoya Protocol (2010) is concerned with the social and economic impact of technology development in food production. The protocol has as its central objective the promotion of social justice in terms of fairness and equality in access to genetic resources and their utilization. The protocol has its provision in article 8(j) and article 15 of the convention and sets out governance provisions with respect to the legal rights of providers of genetic resources and requirements with a view to promote and strengthen use of traditional knowledge and technologies that can be applied to protect biological diversity (Secretariat of the Convention on Biological 2005, Sect. 1, CBD Art 15 and 2011, p. 1). The Nagoya Protocol illustrates how the convention's principles of justice tie in with the concept of sustainable development. The protocol emphasizes the importance of genetic resources to food security, public health, biodiversity conservation, and the mitigation of and adaptation to climate change (Secretariat of the Convention on Biological Diversity 2011, p. 3).

A steadily growing world population, poverty, together with local food insecurity, and lack of access to sufficient food and water for nearly 1 billion people are factors challenging sustainability in global food production (Oosterveer and Sonnenfeld 2012, p. 31). Ensuring availability of a variety of affordable food options is important to avoid problems with food insecurity or malnutrition among economically underprivileged

population groups. Even a small increase in food prices may lead to further social inequity among specific population groups or between developing and developed countries in general (Oosterveer and Sonnenfeld 2012, pp. 50–51). Legal instruments for governance, such as those set out in the Nagoya Protocol, to support local and indigenous farming methods that contribute to conservation of biological diversity through sustainable production, and ensure transfer of knowledge and technology between developed and developing countries, not only set the framework for economic and social sustainability but are also crucial to obtain global food security. It is a complex challenge to govern biological diversity as a collective good with a view to protect biological diversity through conservation while at the same time ensuring food security for a growing world population with huge social disparities. This challenge is further enforced by the problem of climate change. Recent review of scientific data by the Intergovernmental Panel on Climate Change shows that agricultural and food production is likely to be influenced negatively by anthropogenic climate change. In particular, global warming is projected to cause an increased frequency and severity of extreme weather events such as increased frequency of droughts and flooding, which have negative impact on both crop yield and livestock production (Easterling et al. 2007, pp. 275, 299). Expansion of land use with view to sustain or increase food crop production may lead to loss of biodiversity and resources altogether (Easterling et al. 2007, p. 275).

Climate Change as a Challenge to Sustainable Development of Food Production and Consumption

The problem of climate change is perhaps the most urgent environmental problem the global society faces to date. The Intergovernmental Panel on Climate Change's Fourth Assessment Report (AR4) draws a complex image on the challenges to socioeconomic and environmental sustainability of food production and consumption over the next 50–100 years. An average rise

of local average temperatures between 1 °C and 3 °C may lead to an increase of food production overall, but an increase on average above 3 °C is predicted to cause a global decrease in food production. Additionally, agricultural and livestock production is also likely to face challenges from climate change in terms of increased frequency of extreme weather events, such as drought and flooding. Similarly, negative impact of climate change for distribution and productivity in the marine environment is likely to cause extinction of some fish species, which can impact fishery in several regions (Easterling et al. 2007, p. 275).

Climate change represents a major challenge to sustainability in food production and consumption. It is a challenge the objectives of conservation and sustainability in use of genetic resources as these are spelled out in the CBD, as well as to the objectives outlined in the United Nations Millennium Development Goals (<http://www.un.org/millenniumgoals/>) which were established to fight poverty and hunger. There is an urgent need for climate adaptation strategies in food production to establish a sustainable development of food production and consumption. In this context, sustainability involves intensification of production to ensure food security and socioeconomic development, conservation of biological resources, and mitigation of GHG emissions at the same time (The Royal Society 2009, p. xi).

Sustainability as Mitigation and Adaptation: The Climate Convention and the Kyoto Protocol

Production and consumption of food generate GHG emissions, for example, from deforestation to expansion of land use for agricultural and livestock production purposes, livestock production, use of energy from fossil fuels in food production and farming, heating of greenhouses or livestock farms, packaging, transport and cold storage, cooking, and processing of food waste (Oosterveer and Sonnenfeld 2012, pp. 90–91). However, if a development in food production is to be sustainable, it must not only include mitigation and adaptation measures to protect the environment but also at the same time aim at reducing rather than increasing inequalities on a global

scale with view to ensure social and economic development in production and consumption (The Royal Society 2009, p. 11).

The climate convention promotes the idea of intergenerational justice as part of the ethical motivation for the conventions' objectives of climate protection and sustainable development (United Nations 1992, UNFCCC art 3, principle). Similar to the CBD, the climate convention reflects a holistic approach that emphasizes the need for sustainable environmental, economic, and social development (United Nations 1992, UNFCCC preamble). However, balancing the objectives of the two conventions, i.e., conservation of biological diversity (CBD) and conservation of the atmosphere (UNFCCC), in itself is a potential challenge to sustainable development. While mitigation of GHG may contribute positively to conservation of biological diversity overall, there may be cases where the effort to establish mitigation and adaptation can involve trade-offs in terms of negative impact on conservation of biological diversity in local areas. With respect to development of economic and social sustainability, the convention implements the same egalitarian governance principles for justice in distribution and sharing of responsibilities as those included under the CBD.

The principles of fairness and equality lay the ground for the Kyoto Protocol, which concerns the distribution of responsibilities in terms of GHG emission reductions according to the parties' respective capabilities. The Kyoto Protocol was developed in light of the concerns and projections of future impact of GHG emissions outlined by the IPCC in their Second Assessment Report (AR2) from 1995. The protocol was adopted as a legal instrument under the UNFCCC in 1997 (Oosterveer and Sonnenfeld 2012, p. 95). A summary of the emission goals of the Kyoto Protocol is outlined on the official website (http://unfccc.int/kyoto_protocol/items/2830.php). The protocol sets out legally binding emission reduction targets during the period 2008–2012 for the 37 developed countries who have signed up, to reduce their emission of GHG to an average of 5% compared to the emission levels from 1990. The parties of the convention have been negotiating

new targets since 2008, but different interests of stakeholders including social, economic, and environmental interests complicate the task of reaching an agreement.

Citizens' Awareness, Consumer Policy, and Sustainability: Food Miles and Carbon Footprints

The Kyoto Protocol includes three major governance mechanisms: emission trading/carbon market, clean development mechanism (CDM), and joint implementation (JI), all of which are summarized on the protocol's website (http://unfccc.int/kyoto_protocol/items/2830.php). These mechanisms are to promote mitigation in production in a market-based and cost-effective way. With regard to food production, possible strategies to promote mitigation were discussed at the COP 15 climate meeting in Copenhagen and included strategies for sector-specific mitigation through establishment of collaborative research and development and implementation of technologies aiming at mitigation (Oosterveer and Sonnenfeld 2012, p. 95). None of the mentioned strategies were agreed, due to concern for the impact of such governance instruments on international trade (Oosterveer and Sonnenfeld 2012, p. 96).

Other governance approaches may include taxation on products, introduction of standards in food production to promote sustainable and environmentally/climate-friendly food products, or regulations on wastage to promote recycling, etc. However, the successful implementation of such policy approaches relies on public support and awareness of the impact of climate change and the necessity of adaptation measures on international, national, and individual levels.

Concepts such as food miles and carbon footprints have been introduced with the aim to raise consumer awareness about where food products come from and how food production impacts the environment. The concept of food miles was introduced by Prof. Tim Lang in 1996 (Lang 2005). The idea behind food miles is simple: the amount of miles that a food product has traveled gives an indication of its impact on the environment. The concept supports local farming and

promotes a few basic principles that may contribute to lower the negative impact of consumer patterns on the environment: (a) shop local and buy local produce as it would require less miles of traveling from farm to fork; (b) buy seasonal produce as it would require less energy to produce than food products produced in heated greenhouses, for example; and (c) buy fresh produce because it is more likely to state where it is grown. While food miles may be a useful instrument to measure sustainability, focusing on the environmental burden stemming from transport of food products, taking into account miles traveled from farm to fork, the concept also has its limits. Calculating food miles in food products with many different ingredients may be practically impossible, and the concept also does not take into account the environmental impact of the production of packaging used for food transportation (Lang 2005).

Critics of the concept argue that it is too simplistic and gives a skewed picture of the environmental impact of production and consumption of food products. For example, food miles do not take into account how the product is produced or the mode of transportation used. An alternative concept, "carbon footprint" measures the contribution of emission of CO₂ throughout the production chain (Oosterveer and Sonnenfeld 2012, p. 98). Measuring carbon contributions only may not provide a full picture of the environmental impact, and other types of GHG, such as methane from cattle farms, would also need to be taken into account. Yet, while the measuring of carbon footprints is far more complex than food miles, it may provide a more nuanced picture of environmental sustainability in the production of specific food products. Common for these approaches is their appeal to the individual consumer's ethical responsibility to contribute to a more sustainable development in food production and consumption. Examples of governance approaches to promote public awareness include campaigns such as "One Tonne Less" or NGO's campaigns promoting a change to vegetarian diet. Changes towards a more climate sustainable development in food production and consumption are unlikely to happen by way of market-based mechanisms. In fact

such changes are unlikely to happen without regulatory measures. However, consumer and citizen awareness about the impact of climate change and recognition of the need for adaptation in production and consumption patterns are crucial for such governance instruments to be successful.

Conclusion

The modern use of the term sustainability or sustainable development can best be described as an ethical ideal which requires interpretation. The task of determining how a sustainable development can best be obtained is challenged by various ethical and cultural values and by different political beliefs and approaches to governance. The two major international frameworks with relevance for governance of sustainability in global food production and consumption, namely, the CBD and the UNFCCC, set out a holistic approach where sustainability refers to economic growth, promotion of social well-being, and environmental protection. What may be environmentally sustainable may not always be socioeconomically sustainable and vice versa, and thus an important part of establishing a sustainable development is to ensure that while trade-offs are to be expected, these are not to compromise justice in terms of fair and equal distribution of costs and benefits from environmental protection.

While the CBD and the UNFCCC set out similar principles for governance to obtain social, economic, and environmental sustainability, they are established with different objectives in mind. The scope of the two conventions is not conflicting; however, the urgent need for mitigation and adaptation to climate change increases an already complex challenge of ensuring economic growth and social well-being in an environmentally sustainable way.

Transparency in governance approaches, research into the environmental, social, and economic impact of specific governance measures, as well as public debate and engagement are therefore founding criteria for the establishment of sustainable development in food production and consumption in the immediate and distance future. In particular there is a need for more

research and debate on how mitigation and adaptation measures can be combined with already existing initiatives to promote environmental protection and sustainable use of genetic resources. Similarly there is a need for more debate about possible governance instruments to promote sustainable development. The power of consumer campaigns to promote citizen awareness about the impact of individual consumption patterns on the global problem of establishing sustainability in food production and consumption in light of the challenge from climate changes must not be underestimated in this context because the success of governance instruments that can promote changes in local production and consumption practice is reliant on citizens' support of such instruments.

Summary

The idea of sustainability and sustainable development has come to play a central role in governance of food production and consumption over the past 25 years. Sustainability refers to the balancing of availability of environmental resources with consumption with a view to promote economic growth and social well-being. The three sections of the chapter outline the characteristics of the concept and its role in governance and policy of food production and consumption. Sustainability is described as an ethical ideal with a threefold scope aiming at economic, social, and environmental sustainability. Determining what constitutes sustainability in a specific context and how it is best obtained is subject to interpretation and influence from ethical, cultural, and political values and beliefs. The two key international governance frameworks for food production and consumption are examined: the Convention on Biological Diversity and the United Nations Framework Convention on Climate Change. The three dimensions of sustainability represent a complex challenge to governance. While the motivating concern is environmental protection and sustainability, both conventions implement egalitarian principles for justice, emphasizing fairness

and equality as a mode of promoting social and economic sustainability. Climate change is addressed as the major challenge to sustainability in food production and consumption in the future, which is predicted to threaten global food security. The impact of anthropogenic climate change on the availability of genetic resources requires mitigation and adaptation to climate change if food security is to be ensured in the future. Consumer awareness of the impact of production and consumption patterns on climate change plays an important role for support and successful implementation of governance instruments with view to promote sustainability in food production and consumption.

Gendered analysis of consumption patterns; Responsible consumer behavior; Sustainable consumption strategies and gender justice

Introduction

If population and consumption trends continue, the equivalent of two Earths will be needed to support humanity by 2030 (Global Footprint Network 2012). The social, environmental, and economic impacts of global consumptive trends are well documented in the sustainable consumption literature. This entry discusses some of the major food-related sustainable consumption trends and does so by using a gender lens to better understand the gender factors and realities within these trends. The term “sustainable consumption” is used in accordance with the United Nations Environment Programme’s working definition: “The use of goods and services that respond to basic needs and bring a better quality of life, while minimizing the use of natural resources, toxic materials and emissions of waste and pollutants over the lifecycle, so as not to jeopardize the needs of future generations” (Ofstad 1994). Note that the term “consumption” is used herein in its broadest sense, including all three stages of the consumption cycle: the purchase, use, and disposal of products and services. The term “gender” refers to both the perceptual and material relations between women and men, and the term “gender analysis” is taken to mean research that aims to answer questions such as “who does or uses what, how and why?” (FAO 1997). This entry provides a background to gendered perspectives in sustainable consumption discourses before focusing on

three key gender aspects of sustainable food consumption. It then finishes off by looking at gender-sensitive strategies for promoting sustainable food consumption.

Background of Gendered Perspectives in Sustainable Consumption Discourses

History to Gender Studies as a Source of Information

In order to understand how gender has permeated the sustainable consumption discourses over the years, it is first useful to briefly overview the history of gender studies. Four waves have been identified in the development of gender studies and a summary of these stages is presented by Casimir and Dutilh (2003). Firstly, in the early 1970s “liberal individualism” prevailed where the focus of attention was on enabling women, through education and individual support, to minimize differences with men. Secondly, in the late 1970s, the focus shifted to “liberal structuralism,” an approach which addresses the structural or environmental factors (e.g., legislative and policy responses) that prevent equal opportunities. Thirdly, “value difference” or “women’s standpoint” characterized this wave (peaking in the 1980s) and promoted feminine values and alternative ways of living and valuing things. Fourthly, in the 1990s “post equity” or “resisting the dominant discourse” drew attention to post-structuralist thinking and to the ongoing social construction of gender relations. Although gender studies as an interdisciplinary academic field of study dates back over 40 years, it is only in the last 15 years that gender scholars have really started engaging with issues of sustainable consumption.

The Institutional Context

Although a review of international gender policies is outside of the scope of this entry (see Food Policy and Gender entry instead), it is important to understand that much of the agenda setting on debates about gender and sustainable consumption has happened at an international policy/institutional level. Much of this debate has taken place at United Nations world conferences, most

notably, the United Nations Conference on Environment and Development (UNCED) that took place in Rio de Janeiro in 1992. Agenda 21, the program for sustainability for the twenty-first century that resulted from UNCED, concluded that environmental degradation is largely an outcome of overconsumption in the Global North, which is in contrast to the Global South, where it is largely poverty that restricts peoples' consumption choices and leads to environmentally degrading consumption patterns. Gender-related issues were a major focus of Agenda 21, in particular, the commitment to overcome gender inequalities and to ensure equal participation from women.

In terms of gender and consumption analyses focused specifically on food, one of the major institutional players has been the Food and Agricultural Organization (FAO), the United Nations agency that is responsible for agriculture, forestry, and fisheries worldwide. In 1995 they adopted the Plan of Action for Women in Development (1996–2001) (FAO 1995) which presents a framework for ensuring that gender issues become an integral part of their organizational work. The mission driving this Plan of Action was to ensure that all women and men have the support and access to resources that they need to pursue sustainable livelihoods and an improved quality of life.

Following Rio, a Commission on Sustainable Development was established to report on the progress of implementations of the UNCED agreements. In 1999, a report was submitted to the Commission of Sustainable Development which explicitly focused on "Gender and Sustainable Consumption" (Grover et al. 1999). In this report the authors identified the main aspects of the gender and sustainable consumption debate of the time. For example, they state that more poor and illiterate women than men in developing countries have been left out of the "consumption explosion," that the gender perspective has not been properly integrated into international discussions on sustainable consumption, and that the inclusion of gender indicators in sustainable consumption research is recommended. These issues, identified in the late 1990s, are still relevant today (Schultz and Stieß 2009). Part of the reasoning for

this is explained by the fact that sustainable consumption, in the Northern context at least, is still often perceived by policy makers and funding agencies to be gender-neutral, though, as gender scholars explain, this is a really a misconception (Vinz 2009).

The Sustainable Food Consumption Literature

A gender focus has infused the consumption literature on food choice and food practices over the years in a range of academic fields including marketing, history, sociology, anthropology, philosophy, and nutrition. However, much of the literature to date on gender and food is what Weller (2004) refers to as "explicit" gender analyses, that is, gender-specific disaggregated data drawn retrospectively from studies that were not in fact designed to focus specifically on gender issues. This is in contrast to works that utilize an "implicit" gender analysis to specifically address gender issues such as "what degrees of power and influence do different types of consumers have?" The following section considers data on sustainable food consumption drawn from both explicit and implicit gender analyses.

Gender Aspects of Food Consumption

This section is divided up into three parts: (1) the gendered division of labor-work; (2) the gendered body, health, and the social organization of intimacy; and (3) empowerment and access to decision making of women and men (Verloo and Roggeband 1996).

1. The Gendered Division of Labor-Work

This first dimension refers to "norms, rules and practices in the field of labor, where asymmetrical distinction is produced between women and men, between paid and unpaid labor, between work inside and outside the home, and between male and female tasks and professions" (Verloo and Roggeband 1996, p. 6). Women and men have different employment patterns and socioeconomic situations, both which have direct and indirect implications on food consumption patterns. For

example, with regard to employment, in industrialized countries, the proportion of men of working age in paid employment exceeds that of women. Of the population of working women, however, considerably more work part-time hours than men. Wages are lower on average and women of working age are more likely to live in households at risk of poverty (women who live alone with a dependent child are particularly vulnerable).

Time budget surveys conducted in European countries show that despite increasing participation of women in the paid labor market, and a resulting decrease of traditional gender roles, women still are assigned the core of housework management activities and, as a result, suffer more from time scarcity than men. Empirical research shows, for example, that on average women are responsible for 80% of the consumption decisions made in private households and are the person that is primarily responsible for meal planning, buying, and preparing food. In developing countries, it is also women who are primarily responsible for the provision and preparation of food for the family, though the tasks involved in these processes are obviously of quite a different scope and nature to that of women in developed countries. In this case, it is food poverty that leads to peoples unsustainable food consumption patterns, due to a lack of options and choices available to them.

Increased participation of women in the workforce in the Western world has resulted in a sharp rise in demand for convenient foods. Meal planning is now often done late in the day, and the supermarket is increasingly used as a pantry, with consumers stopping off on the way home to get whatever they feel like having for dinner that night. As well as the obvious increased negative environmental effects on increased travel to shops, lack of meal planning is often touted as one of the key reasons for the huge amount of food that is wasted at a household level. In addition, the foods that are bought late in the day for meal that evening are often time-saving products that are quick and easy to cook but that often come with a higher environmental price tag due to factors such as increased processing, transportation, and packing.

Empirical studies in industrialized countries have compared consumers' attitudes, values, and preferences toward sustainable food products, and clear gender differences have been repeatedly detected. Women, for example, have been shown to have a higher level of environmental awareness than men, despite the fact that they tend to report that they feel less informed than men about climate change and environmental issues. Women also generally tend to express a higher level of engagement with environmental issues generally and for environmental issues surrounding food consumption more specifically. Not only do they tend to have more environmentally friendly attitudes, they also are more inclined to act in a more environmentally friendly manner in their consumption behaviors. Research in different countries has repeatedly shown, for example, that women are most likely to buy organic food products (especially middle-aged women, with dependent children, who have high incomes and are well educated). Women have also been shown to be more skeptical than men regarding new technologies and their potential impacts and risks. Research indicates that women generally do not favor genetically modified (GM) food products and that they are more willing than men to pay a premium for products that are GM-free. Early ecofeminism writings attempted to provide some justification for such gender differences in environmentally friendly attitudes and behaviors. In such writings, women are depicted as nurturing and peaceable (due to their domestic and reproductive capacities) in contrast to men who are considered to be powerful and destructive. In fact, nature is even sometimes referred to in this body of literature as a "feminine principle."

2. The Gendered Body, Health, and the Social Organization of Intimacy

Health, reproductive health, vulnerability, and bodily needs are all important aspects in this dimension.

The concept of intimacy is described as "norms and institutions around sexuality, extending to the social organization of personal

relationships, procreation and motherhood” (Verloo and Roggeband 1996, p. 6).

Given that women are the both the lead providers of food and have higher care responsibilities than men in the household, they play a crucial role in managing the families nutritional status and overall health. This responsibility is reflected in research results which repeatedly show that women tend to pay higher attention to hygiene standards in food preparation and provision. However, development interventions, especially in the Global South, aimed to improve access to safe food, often bypass women (FAO 1997). Programs designed to suit women’s needs, education, and cultural backgrounds that provide technical information on improving the quality, nutritional status, and safety of food at the household level are needed. Such programs might focus, for example, on home gardens and livestock rearing, which improve access to suitable, low cost, good quality, safe, and nutritional foods. Foods grown at this local level not only lead to greater opportunities for food sovereignty but also increase consumption of sustainable, environmentally friendly foods (that tend to require much lower levels of pesticide and have reduced food miles than alternative products).

Another issue affecting some women in the Global South is health during pregnancy and lactation. In reproductive years, women have special nutrient requirements in order to assure their own health and that of their child though many societies fail to recognize these specific needs. For example, in some societies, discriminatory practices still exist which prioritize feeding male members of the family before females (often including young girls). Such consumption patterns are obviously unsustainable (in the broad sense of the word) as they have the potential to affect health and do not contribute to improved quality of life for women.

There is much literature which discusses gender-specific differences in eating behaviors (see the entry on ► [Gender Norms and Food Behavior](#)), though this for the most part does not have an explicit sustainability focus. Nevertheless, sustainable consumption strategies must take into account the fact that women and men

do eat in a different way. Gender differences in food preferences seem to begin during childhood. Findings from studies on this phenomenon suggest that females and males assign different meanings and values to different types of foods which results in females and males eating differently. Women tend to eat healthier, have higher nutritional knowledge, and show higher preference for eating foods that are included in common dietary guidelines, which means they tend to eat more fruit and vegetables than their male counterparts. This concern for health issues can in part be explained by the fact that women are primarily responsible for care duties. Another explanatory factor for why women are more food literate than men is due to the fact that women are often involved much earlier than men in food-related activities. Men, in contrast, are often cited as tending toward pleasure foods that taste good. They also eat more meat (both more often and in larger quantities) than women, which is significant from a sustainable consumption viewpoint, given that meat production accounts for almost a fifth of all greenhouse gasses according to FAO data. Though this is in part due to role orientation, in the cultural identity literature, this has also been explained by the symbolic meaning of meat (which infers strength and power). An interesting study that highlights an example of gendered differences toward certain food types is a study on comfort food choices (Wansink et al. 2003). Results showed that most men prefer hot meals to snacks (the three foods most men considered to be their favorite comfort foods were ice cream, soup, and pizza or pasta, which was in contrast to women for whom it was ice cream, chocolate, and cookies). Many men reported that when they ate these foods, they felt “spoiled,” “pandered,” “taken care of,” or “waited on,” indicating that generally they associated these foods with being the focus of attention from either their mother or wife. Women, on the other hand, seem to have the opposite preference for a similar reason (i.e., they liked snack-like foods that were hassle-free).

3. Empowerment and Access to Participatory Decision Making of Women and Men

The kind of aspects that are related to this third gender dimension include empowerment of women and men as consumer-citizens, participation of women and men in implementation of sustainable consumption instruments in all stages of the policy cycle, access as consumer-citizens to decision making, and participation of consumer-citizens in institutional settings of implementation. This dimension is particularly relevant for changing consumers' food behaviors (Schultz and Stieß 2009). It is important that more women become involved in decision making at both governmental level and at the level of international policy making, to find solutions to sustainable food consumption issues. Greater representation of women is also needed in food industry boardrooms and in food companies themselves (especially in scientific positions) to help address food sustainability issues from a women's perspective.

As has been mentioned, worldwide, women are still primarily considered to be the household manager, especially in terms of food provision and preparation. As such, they continue to play a key role to controlling a considerable share of the total carbon emissions produced by a household. This means that they are, and must continue to be, key actors for sustainable consumption strategies (WEN 2007). The most obvious way that consumers can act to promote sustainable food consumption is by voting with their shopping dollars (i.e., by "boycotting" or "buycotting") when they purchase food products and services (note that this is referred to in the literature as engaging in political consumerism). It is important to empower all consumers so that they are able to engage in acts of political consumerism in an informed manner. This can be done in many ways, the most obvious being providing them with full information about the sustainability credentials of the product on its label.

Governments, industry, and consumer groups alike promote this sort of "bottom-up" approach to achieving sustainable consumption, where the consumer is positioned as the all-powerful decision-maker and the mandate is for industry to provide as wide of a choice of products as possible, so that the customer can decide which

one to purchase. The problem, however, with this sort of approach is that it places the responsibility for sustainable consumption on the shoulders of individual consumers. As has been already stated, in many cases when it comes to food buying, these individuals tend to be women, many of whom are already feeling under immense time pressure due to juggling domestic, care, and paid-labor activities. The image of the confused consumer standing in front of the fresh salad section of the supermarket trying to work out if it is more "sustainable" to buy the organic lettuce, packed in a plastic bag and flown in from overseas, or the conventional (nonorganic), but local, alternative is all too familiar. Without providing full information about the total amount of materials used in the production, transportation, and storage of these products (e.g., water, energy, and pesticides) and the total amount of waste outputs generated in these same process (e.g., greenhouse gas emissions, food wasted), the consumer is, in reality, inadequately equipped to make this sort of decision with any accuracy. A move away from total privatization of responsibility, that is, from leaving it completely up to the consumer to bear the burden for being sustainable in their consumption choices, requires that some of the responsibility for sustainability is pushed back onto other players in the food industry. Cases of this happening can be seen already. Examples include retailers "editing out" (i.e., not stocking) unsustainable food brands and products such as cafes that choose not to stock coffee that is not Fair Trade certified and supermarkets that choose not to stock certain types of unsustainable fish. Other institutions (e.g., governmental bodies) could also take more responsibility for helping people to consume sustainably, again lifting some of the burden off the shoulders of consumers. Examples of ways they could do this include developing criteria that would allow food products to be more accurately evaluated based on sustainability criteria, devising policies that would encourage the reduction of overall consumption levels or encourage sustainable buying, or by outright banning certain unsustainable food products in some circumstances.

Gender-Sensitive Strategies for Promoting Sustainable Food Consumption and Future Research Needed

Gender differences must be taken into account in order to be able to successfully implement sustainable food consumption strategies. Although strategies and campaigns promoting sustainable food consumption are often devised to be gender-neutral, research shows that gender responsiveness to these campaigns can be remarkably different. The sustainable campaigns which do contain a gendered aspect are generally targeted specifically at women because of their more environmentally friendly consumption attitudes and behaviors.

Given this, it would be useful to search for and communicate specifically sustainable consumption behaviors around food that are more gender available to men (Schultz and Stieß 2009). Furthermore, these same authors argue that it is important that sustainable consumption campaigns are checked to make sure that they do not contain any implicit moralization of women's responsibility (i.e., by fading out gendered patterns of responsibility for paid and unpaid labor and housework).

There is much scope for further research on creating gender-sensitive strategies for sustainable food consumption. Areas particularly worthy of further attention include the following:

- Finding ways to ensure that gender perspectives are better integrated into international-level discussions on sustainable consumption
- Generating gender disaggregated databases and gender-sensitive indicators of food consumption
- Conducting gender-specific surveys about environmental motivation and behavior in relation to food behaviors
- Considering how sustainable consumption patterns are shaped by the relationship of gender with further variables such as lifestyles, values, and other sociodemographic variables (e.g., age, marital status)
- Considering gendered income allocation for nutrition
- Using gender disaggregated data on food and nutrition in the design of policies, programs, and interventions for sustainable food consumption
- Supporting the development of gender-sensitive strategies for sustainable food consumption in order to not increase women's workload

Summary

The consumer behavior literature quite clearly indicates that gender is a strong determining factor for many different types of food attitudes and behaviors. Consumption has historically been associated with women and the private sphere. Even today, women are responsible for on average 80% of the consumption decisions made in private households and are the person that is primarily responsible for meal planning, buying, and preparing food. While this does put them in a good position to be able to do something to improve the sustainability of food consumed by private households, there are a number of ethical issues which are of concern as this entry has highlighted. Three of the key ethical issues related to gender and sustainable food consumption discussed in this entry are ensuring that (1) all women and men have access and support to resources they need to pursue sustainable livelihoods and improved quality of life; (2) the responsibility for achieving sustainable food consumption is shared equally between women and men, as well between individual consumers and other players in the industry such as retailers and governmental agencies; and (3) sustainable consumption campaigns do not contain implicit moralization of women's responsibility and that ways are found to better communicate messages about food-related sustainable consumption behaviors to men.

Sustainable Food Procurement

Mark Stein
Salford University Business School,
Manchester, UK

Introduction

This entry endeavors to give an overview of ethical issues relating to public procurement of food for the public sector – principally schools and hospitals, as well as care homes, prisons, and office canteens.

Public procurement has multiple objectives. Procurers must seek to buy food at an affordable price and delivered in adequate quantities and at the required time. Food must meet government nutritional and food safety standards.

Ethical issues are also often discussed under the concept of *sustainable* procurement, with reference being made to environmental, economic, and social sustainability.

The most important environmental considerations include protecting biodiversity, especially by introducing organic food, and reducing greenhouse gas emissions, by reducing food miles or perhaps by reducing meat consumption.

The most important economic and social considerations include:

- Promoting animal welfare
- Supporting local food producers
- Promoting better employment conditions among employees in the food chain
- Buying fair trade products
- Providing children with healthier school meals
- Teaching children about healthy food

Ethical Objectives Are Encouraged by the New EU Public Procurement Directive

The new EU Public Procurement Directives became law in March 2014. All EU member states have 2 years to pass legislation to transpose them into national law.

Contracts must now be awarded not simply on the basis of lowest price but based on the “most economically advantageous tender” (MEAT). This will enable public authorities to put more emphasis in the award procedure on quality, animal welfare, environmental considerations, social aspects, or innovation while still taking into account the price and life-cycle costs of what is procured.

The new regulations will benefit small and medium enterprises (SMEs) by encouraging buyers to break large contracts into smaller lots. The new rules will see much simpler and more streamlined procurement processes, which could save SMEs up to 60% of bidding process costs.

The new regulations will also encourage procurers to buy fair trade products (see below).

Promoting Farm Animal Welfare

A common way in which public procurement can aim to protect farm animal welfare is by requiring meat or dairy products to have been produced according to a system of farm assurance which guarantees certain minimum standards of welfare.

In the UK Red Tractor is the leading farm assurance scheme, and public procurement tenders often specify that the meat or other produce must comply with Red Tractor standards even though it may have been certified by a different certifying body in another EU member state.

The UK’s Sustainable Development Commission commissioned an analysis which gave a limited endorsement of Red Tractor, saying that its

standards do a good job of assuring food safety, animal welfare and to a lesser extent, environmental imperatives. They also generally cover safe working environments and appropriate training where these relate to food safety. However they do not

cover... other key aspects of sustainable development – viable livelihoods, environmental improvements, rural cultures and economies, nutritious food and accurate information about food, and local foods... The levels set for some of the ... standards are well below those that the UK Sustainable Development Commission would argue are necessary in sustainable food production. (Sustainable Development Commission 2005, p. 5)

Public procurers in the UK have followed a wider change in public buying habits by switching to free-range eggs.

The keeping of laying hens in battery cages has been banned throughout the EU from January 1, 2012. This decision reflected widespread public concern about the suffering of chickens in battery cages. Under the new rules, caged birds will have twice the space they had previously although still less than free-range chickens.

The Sustainable Development Commission reviewed the reasons for the massive growth in UK consumption of free-range eggs – from 7% of total market in 1987 to 30% in 2005 – and concluded that the shift occurred due to producer response to the salmonella health scare in 1988. It was reinforced by public concerns about animal welfare. There was strong media support for change, egg quality was the same or better, and the price difference was small.

Supermarkets were quick to react to the salmonella health scare and offer customers a free-range choice of eggs. Retailers and some restaurants also use free-range egg products as part of public relations activity. For example retailer Marks and Spencer, and fast food retailer, McDonalds who have a free range only offer ... Egg producers have responded to the higher demand and higher margins offered by free-range and the mix of production methods have continued to shift towards free range year-on-year since 1988. (Sustainable Development Commission 2006, p. 14)

Support for Small and Local Food Producers: The UK, Finland, and Sweden

There are widespread initiatives in the UK promoting sourcing of local and organic food for school kitchens, and these have been promoted by several initiatives over the years – particularly the Public Sector Food Procurement Initiative

between 2003 and 2009 and the Food for Life Partnership since 2007.

Finland has provided free school meals to all school children since 1943, and this has been an important dimension of the welfare state. The government's sustainable development and procurement strategies encourage procurement of local and organic food. A telephone survey of Finnish municipalities shows that procurement of local and organic food is a widespread practice, although there are opportunities to increase such procurement. The report concluded that:

If public sector kitchens really want to use local food, it requires a new kind of thinking. It would require readiness to genuinely cooperate with the producers for instance by developing their products into something that kitchens can use for their needs. Joint meetings between kitchen buyers and the producers require time initially but as the cooperation matures, there will be less need for meetings. (Muukka et al. 2008, p. 26)

Sweden resembles Finland in terms of strong government sustainable development policies and a system of universal free school meals. Special distribution arrangements to assist small food producers by lifting the logistic burden of distributing to large numbers of public sector kitchens are practiced by significant numbers of municipalities in Sweden and the UK. Division of contracts into lots is another practice which assists small producers and is quite widespread in Sweden and the UK.

Support for Small and Local Food Producers: Farm to School in the USA

In the USA "Farm to School" is a nationwide program which helps bring fresh, local produce to school cafeterias. The first USDA census has revealed that 43% of US school districts – or about 38,600 schools – bought local produce for their students during the 2011/2012 school year. This reflects substantial growth of "Farm to School" food purchasing over previous years.

Many chefs have switched away from buying in pre-prepared packaged meals toward cooking with fresh ingredients. This is seen as providing healthier and higher-quality food.

Small producers may struggle to provide the volume, variety, and regularity of products required for the school kitchens. They may also struggle with the logistical challenge of delivery of food to large numbers of schools. A widespread development within the USA has been the creation of local food hubs to address the distribution problems faced by small suppliers:

A major obstacle to localization is the lack of economic, organizational and physical structures of the appropriate scale for local aggregation and distribution of food. Local food hubs are emerging as an important tool for overcoming that obstacle by pooling food products from a number of smaller farms and delivering them to grocery stores, schools, hospitals and restaurants. (Cleveland et al. 2014, p. 26)

Distribution of food is thus separated from supply, making it easier for smaller food producers to compete in the marketplace.

Teaching Children About Healthy Food

Farm to School tends to promote healthier eating habits. Visits to farms play an important role.

When students have the opportunity to spend time on farms, to get to know farmers and to see, taste, touch and smell food in its natural state, they are far more willing to try it raw or prepared at mealtime, ask for it at home, incorporate it into their own diet and be willing to try new and different foods when they are offered. ... (Davis and Hudson 2011, p. 179)

Cookery classes and creation of school gardens are other ways in which Farm to School promotes children's better understanding of food and healthy eating. Similar work is being done in the UK by the Food for Life Partnership. Persson Osowski et al. (2013) discuss the role of the "pedagogic meal" in Sweden, where school meals are intended to be a teaching occasion in which children learn about food and meals – health, nutrition, and table manners. In Finland government policy also encourages nutritional education, learning of table manners, school gardening, and cookery lessons.

Environmental Benefits of Local Food Supply

The notion has become widespread that local food is better for the environment – specifically because long-distance food transport (food miles) leads to greater greenhouse gas emissions. The “food miles” concept was coined and developed by Professor Tim Lang in the early 1990s. He said in 2009 that “food miles” is

woven into the language now, a shorthand for a debate, a perspective. In the early 1990s, it was very helpful to get people to realise that food wasn’t local anymore but had become globalized and industrialised, trucked about endlessly – and often needlessly – before reaching the plate... To some extent the Food Miles metric isn’t accurate; carbon or greenhouse gas emissions are better measured using Life-Cycle Analysis. (Harper 2009, p. 21)

Some researchers have however argued that the view that food’s environmental impact depends on distance traveled is an enormous oversimplification. Edwards-Jones (2010) shows that there is no simple relationship between local foods and lower GHG emissions. If one compares tomatoes grown in heated greenhouses in Britain with those grown without artificial heating in Spain, British produce will have incurred fewer food miles, but transportation may be quite a low percentage of the total carbon footprint.

However the belief that purchasing local food is always more environmentally friendly is still held among influential decision-makers at both national and local level.

The Local Trap

Born and Purcell (2006, p. 195) have coined the phrase “the local trap,” referring to

the tendency of food activists and researchers to assume something inherent about the local scale. The local is assumed to be desirable; it is preferred a priori to larger scales. What is desired varies and can include ecological sustainability, social justice, democracy, better nutrition, and food security, freshness, and quality... [T]he local trap is misguided and poses significant intellectual and political dangers to food systems research.

Winter (2003, p. 30) points out in his study of food purchasing patterns in five rural localities of England and Wales that

the patterns of food purchasing revealed, with local food figuring more highly than organic, illustrate a defensive politics of localism rather than a strong turn to quality based around organic and ecological production.

He gives the example of a dairy farm in Devon with widespread local sales:

The farm is not organic, nor are environmental and food safety considerations used to market the product. Indeed the farm is intensively managed with high inputs of nitrate fertilizer and in common with many west country dairy farms a recent shift to forage maize with attendant problems of soil compaction and/or erosion.

It must not be assumed that localization of food systems necessarily equates to promotion of environmental sustainability and social justice. The opposite may be the case.

The challenge is to combine food localization with environmentally and socially desirable food production methods, such as better pay and working conditions for farm workers and minimizing of environmentally destructive farming methods.

Fair Trade: For the Global South

Fair trade refers to the movement to secure better prices, decent working conditions, local sustainability, and fair terms of trade for farmers and workers in the developing world. Consumer sales of fair trade products from the Global South have grown rapidly in the Global North.

The main fair trade food products are tea, coffee, sugar, fruit juice, bananas, chocolate, wine, cereal bars, and biscuits. The limited purchasing of fair trade products by public authorities can be explained by two factors:

- Government guidance on EU procurement rules which until very recently discouraged public authorities from giving any form of preference to fair trade products in public procurement

- The limited range of fair trade products available and limited demand for less healthy foods like chocolate and sugar

Fisher and Corbalán (2013) predict that the forthcoming change to the Public Procurement Directives will facilitate the uptake of fair trade products by public authorities.

Agricultural Working Conditions: What About Fair Trade for the Global North?

The suggestion has been made that farmers and workers in the Global North should also be able to benefit from fair trade – given that pay and working conditions are often very poor. There have been academic studies in the USA and Europe which have shown that some consumers are willing to pay extra for food products if they have been grown under fair labor conditions and the term “domestic fair trade” has been coined (Howard and Allen 2008). There have been attempts to develop domestic fair trade in the USA – particularly California. No widely accepted “domestic fair trade” label has yet emerged in Europe.

Up till now public procurement in Europe appears to have made hardly any attempt to address the problem of poor labor conditions in farming and other food production. One exception is the Manchester Veg People (MVP) cooperative, established in 2009. MVP is a cooperative of organic growers and buyers – restaurants and caterers – created to increase access to sustainable food in Greater Manchester and create a more stable market for small local food producers. The model is based on fairness, with prices based on costs of production and the risks involved in food production shared by the members, through creating relationships of trust and understanding between growers and buyers. At present MVP operates on a very small scale. Its most important customer is from the public sector – the University of Manchester.

Reducing Meat Consumption

Several academic studies emphasize that of all food products, red meat has the highest carbon

footprint and the greatest environmental impacts, as well as having negative impacts on human health when consumed in large quantities.

In historical perspective meat consumption in the developed world has risen dramatically over the last 200 years. Ruminant animals – cattle and sheep – emit methane, which is a particularly potent greenhouse gas. A recently published study of 2,253 Dutch consumers reports that:

Empirical studies of the meat-consumption frequency of Dutch consumers show that, apart from meat-avoiders and meat-eaters, many people are meat-reducers that eat no meat at least 1 day per week. . . . Given the enormous environmental impact of animal-protein consumption and the apparent sympathy of consumers for meat reduction, it is surprising that politicians and policy makers demonstrate little, if any, interest in strategies to reduce meat consumption and to encourage more sustainable eating practices. (Dagevos and Voordouw 2013, p. 1)

A “Meatless Mondays” movement began in 2003, and this is now promoted by many groups in Europe, Japan, the USA, Britain, Canada, Israel, and Australia.

For example, the Belgian Municipality of Ghent won support of local people for its Veggie Day campaign. Vegetarian days have also been tried quite extensively in Finland and with some success.

Cordts et al. (2014) describe a survey of 690 German consumers which shows that animal welfare and human health arguments are most effective in reducing meat consumption.

There is strong support for vegetarian days in public catering in certain German and Swedish cities. However, the German Green Party’s 2013 General Election Manifesto included a policy of introducing vegetarian days in all public catering, which aroused intense opposition among carnivores which is thought to be one of the main reasons for the German Greens’ poor election result.

Until now support in the UK for Meat-Free Mondays has also been limited. It has been adopted by a small number of individual schools in London, Buckinghamshire, and particularly Liverpool. Two local authority catering services appear to have adopted Meat-Free Mondays –

with very little publicity, as if the managers are concerned that this could be unpopular with parents.

In June 2014 the UK Department of Education published a 16-page booklet providing guidance on the revised school food standards. The standards – which schools will be required to follow – will oblige them to provide meat or poultry at least 3 days a week.

Following the standards, there are “top tips” which include the first ever official suggestion that schools can “encourage all children to have a meat-free day each week, using alternatives such as pulses, soya mince, tofu, and Quorn” (School Food Plan 2014, p. 6).

Organic Food: Environmental Benefits and Animal Welfare

Organic food sales have risen worldwide and in Europe. The European organic market more than doubled between 2006 and 2015. During 2014–2015 double-digit growth rates for organic markets were seen in ten European countries. This included large countries such as Germany, France, and Italy, as well as smaller countries such as Austria and Belgium (Willer and Lernoud 2017, Fig. 84).

There is considerable academic debate about whether organic food is more nutritious than conventional food – with emphatic views expressed on both sides.

Proponents of organic agriculture also argue that it promotes greater biodiversity, soil fertility, and animal welfare and uses less energy than conventional agriculture. Countries with strong government policies supporting organic food in public catering include Italy, Sweden, Denmark, and Finland.

Organic Conversion: The Role of Street-Level Bureaucrats

Since 1995 the Danish government has been encouraging increased usage of organic food in public catering. Mikkelsen and Sylvest (2012)

describe organizational changes in public catering linked to implementation of this policy, focusing on 43 projects which received government grant assistance in different municipalities, eight of which involved over a hundred food service units. Three quarters of the projects succeeded in reaching their goals of significantly increasing organic food. The study looked at the roles of the people who actually implement policy – “street-level bureaucrats”:

- Organic food is significantly more expensive, and catering managers have had to convert to organic without an increase in their food budget by making savings elsewhere.
- The shock of organic conversion has stimulated catering managers to rethink kitchen organization and procedures which might otherwise have gone unquestioned and to find savings.
- Cost-cutting menu planning has in many cases resulted in more expensive meat cuts being replaced by cheaper vegetable products.
- The food being served in the kitchens is more nutritious and less is wasted.
- Kitchen personnel acquired new skills and experienced increased pride and engagement in their work.

The article concludes that the personal preferences and attitudes of the street-level bureaucrats seem to play an important role.

Similarly, Post and Mikkola (2012) carried out 46 structured telephone interviews with members of a Nordic network for healthy and sustainable catering, endeavoring to increase usage of organic food. Their article emphasizes the need for dedicated individuals, who are personally motivated to promote the sustainability agenda.

Conclusions

The most widely practiced ethical/sustainability theme in public procurement is supporting local food producers.

Other themes which are widely practiced are:

- Promoting farm animal welfare
- Teaching children about healthy food
- Introducing organic food into public catering

Promoting fair trade for the Global South is a minor priority for most public procurers because of the very limited range of foods which is available under the fair trade label.

The pressure to buy food as cheaply as possible runs counter to any aspirations to promote better agricultural working conditions.

Major ethical dilemmas relate to support for local producers and for meat consumption.

Support for local producers may well imply purchasing of local produce (e.g., red meat), which has a very high carbon footprint, and its production may have major negative environmental impacts.

Procurers may be aware of the environmental and health benefits of reducing meat consumption but feel unable to act on this knowledge. They may be worried that local farmers would protest. A further concern is that the consumers of the public food service may well resist any reduction in meat provision, for example, by refusing to buy the meals, thereby threatening the viability of the public food service.

Introduction

Synthetic biology is a field of research that concentrates on the design, construction, and modification of new biomolecular parts and metabolic pathways using engineering techniques and computational models. By employing knowledge of operational pathways from engineering and mathematics such as circuits, oscillators, and digital logic gates, it uses these to understand, model, rewire, and reprogram biological networks and modules. Standard biological parts with known functions are catalogued in a number of registries (e.g., Massachusetts Institute of Technology Registry of Standard Biological Parts). Biological parts can then be selected from the catalogue and assembled in a variety of combinations to construct a system or pathway in a microbe. Through the innovative reengineering of biological circuits and the optimization of certain metabolic pathways, biological modules can be designed to reprogram organisms to produce products or behaviors.

Synthetic biology is what is known as a “platform technology.” That is, it generates highly

transferrable theoretical models, engineering principles, and know-how that can be applied to create potential products in a wide variety of industries. Proponents suggest that applications of synthetic biology may be able to provide scientific and engineered solutions to a multitude of world-wide problems from health to energy. Synthetic biology research has already been successful in constructing microbial products which promise to offer cheaper pharmaceuticals such as the antimalarial synthetic drug artemisinin, engineered microbes capable of cleaning up oil spills, and the engineering of biosensors that can detect the presence of high concentrations of arsenic in drinking water.

One of the potential benefits of synthetic biology research is in its application to biofuel production. It is this application which is the focus of this entry. The term “biofuel” has referred generally to all liquid fuels that are sourced from plant or plant by-products and are used for energy necessary for transportation vehicles (Thompson 2012). Biofuels that are produced using synthetic biological techniques reengineer microbes into biofuel factories are a subset of these.

Entry Road Map

This entry begins with a short historical background that focuses on the initial ethical support and justification for synthetic biofuel research, the impact of this research on public discussion of synthetic biology, and the distinction between it and genetic engineering. The distinction between *first-* and *second-generation biofuels* is introduced. This is followed by a survey of current research innovations using various *microbial factories*, including bacteria, yeast, and oil (oleaginous) algae.

Ethical considerations associated with synthetic biology research in general and its application to biofuel production in particular will be reviewed. General responses by opponents of all forms of synthetic biology include the claim that this type of technology aims to “play God” and that the unnaturalness of it intervenes in the natural world in ways that are unethical and should

therefore be avoided. This justification has been used to attempt to restrict or stop new approaches to biofuel technology that aim to control and co-opt natural selection in order to produce a stable product.

Proponents of this synthetic reengineering suggest that these ethical concerns are unfounded. Synthetic biology merely extends the mechanisms by which artificial selection can be controlled and modified beyond traditional approaches to selective breeding.

Ethical considerations that apply specifically to synthetic biofuel research and technology include issues in the design, construction, implementation, marketable production, and assessment of synthetic biofuel production when compared to food crop biomass-based biofuels. Motivations for synthetic applications that focus on the growing concerns over the high cost of production of crop biomass-produced biofuels and the subsequent food shortages that followed, widely framed in terms of the food versus fuel debate, will be discussed. In addition to these, the ethical issues surrounding the potential impact on human health and the environmental consequences of intentional and accidental release of synthetic products of biofuel research will also be covered.

Ethical discussion surrounding synthetic biology and biofuels is, like the research and technology itself, still emerging. An outline of the current efforts of commissions and consortia set up in the United States and the United Kingdom that have promoted the scientifically informed open exchange of ideas between scientists and the public on ethical issues relating to synthetic biology research and application are discussed.

Historical Background

Synthetic biofuel production seeks to provide less expensive, cleaner, and greener sources of energy than currently used traditional fossil fuels. Perhaps because of this, it has been one of the most publically accepted and perhaps most promising applications of synthetic biology. In a field of research where descriptions of the products of synthetic biology are frequently reported as

“designer organisms,” “Frankencell,” or the result of “playing God,” discussion of synthetic biofuels seems less controversial. Its potential benefits are often weighed up against its potential costs: “synthetic biology poses a conundrum because of its double-edged ability to both wreak biological havoc and perhaps wean civilization from dirty twentieth century technologies and petroleum-based fuels” (Weiss 2007).

Although sometimes referred to as genetic engineering, synthetic biology differs from genetic engineering in terms of scale, techniques of manipulation, and application. Genetic engineering focuses on the alteration or manipulation of a few characteristics of an organism that results in transgenic hybrids or genetic chimeras that possess genes inserted from other organisms. Whereas, synthetic biology seeks to reconfigure, design, and construct new pathways, whole processes, or novel systems for the purpose of achieving some desired biosynthetic activity or phenotype (Alper and Stephanopoulos 2009).

First-Generation Biofuel Production Strategies

Current research aims at producing a cleaner biofuel alternative to those that are currently agriculturally produced using food crops. These crop-based biofuels, often referred to as *first-generation biofuels*, rely on agricultural crops as biomass to produce sugar or starch from corn, wheat, or barley and convert this to ethanol through fermentation and distillation processes or rely on oilseed crops to produce triacylglycerols that are then chemically converted to biodiesel.

One of the most heated recent ethical discussions focusing on the use of first-generation biofuel production has been the so-called food versus fuel debates. These have typically centered on discussions about the appropriate use of agricultural land – should agricultural land be used for generating fuel instead of food? The decisions of some farmers to plant food crops such as maize for the purpose of harvesting the biomass to sell to biofuel producers have been controversially linked with an increase in food cost and food shortages.

In addition to the fuel versus food debates, discussion has also focused on the production costs themselves and their impact on the environment. First-generation agricultural crop-based biofuel production demands arable land use and water use in irrigation and provides a fuel source that may not be as cost-effective or renewable as the potential second-generation biofuels which do not require either arable land, irrigation, or the displacement of food crops (Börjesson and Mattiasson 2008; Preston 2008).

Second-Generation Biofuel Research Strategies

Instead of relying on food crops as the source of fuel, synthetic engineered alternatives, or *second-generation biofuels*, rely on using the redesigned microbial cell as the source of biofuel production. Synthetic biological engineering is sometimes referred to as *white biotechnology* due to its focus on renewable energy sources and the reduction of negative environmental effects and the potential biodegradability of its engineered products.

In providing more sustainable avenues of biofuel production, these second-generation synthetic biofuel alternatives present a way to circumvent the controversial fuel versus food debates that have been widely discussed in the various news media and in local and global ethical discussions.

These and other debates have led private and public support of synthetic biology research into carbon-neutral synthetic biofuel alternatives that may not only provide solutions to the energy crisis but also provide a way to circumvent the continued degradation of the environment through the burning of fossil fuels and greenhouse gas emissions (Martin et al. 2003).

Microbial Factories of Biofuel Production: Prospects and Problems

Synthetic biology builds on past successes and failures – what works in terms of both modules

that are highly interchangeable as well as methods and pathways are reused in new projects. Earlier research on another application of synthetic biology research, the production of synthetic artemisinin, provided guidance on how microbes can be used and their tolerance of different types of chemical products. Synthetic artemisinin is perhaps one of the most widely discussed success stories of synthetic biology research. Artemisinin is an antimalarial drug which is now sold commercially by Amyris Biotechnologies which now uses similar technology in the search for a scalable renewable biofuel (Amyris Biotechnologies 2013).

Development of second-generation biofuel requires the use of a microbial factory organism such as the yeast, *Saccharomyces cerevisiae*, the bacterium, *Escherichia coli*, or the single-celled green alga, *Chlamydomonas reinhardtii*, which is then redesigned to produce certain products. To do this, synthetic biology researchers use parts with known functions from a variety of organisms. A catalogue of these parts is used to choose which components can be put together in the cell to build new pathways and as a result produce new chemical products.

One of the initially most promising organisms to construct a potential biofuel factory was the yeast *S. cerevisiae*. This is widely used to produce ethanol from sugar in the brewing of beer. As it is also an organism frequently used in genetics and synthetic biology research, its metabolic pathways and functions are well characterized. Its ability to produce ethanol made it appear to be a good beta test for a new biofuel factory. *E. coli* is another common organism for use in synthetic biological research in virtue of its proven ability to accept genetic modification with the introduction of foreign genes, the tendency to maintain hybrid networks, and the production of a variety of products (Martin et al. 2003). For instance, Fuzhong Zhang, James Carothers, and Jay Keasling have successfully designed a strain of *E. coli* that implements a biosensor for a metabolite that plays a role in the production of biofuel products using glucose (Zhang et al. 2012). By adding the biosensor to the engineered pathway, their new strain of

E. coli is capable of trebling the amount of fuel produced (Zhang et al. 2012).

Relying on the knowledge of these and other microbial pathways and modules means that these parts can be both modified and transferred into other organisms to reengineer it to produce a higher ethanol yield or to produce ethanol by consuming a different sugar (such as hexose or xylose) rather than what it would normally utilize (e.g., glucose).

The current research trend in publically and privately funded projects is to investigate the potential use of various species of algae for biofuel production. Algae produce lipids (oil) as a by-product of the process of photosynthesis. The hope is that once the means of harnessing this store of energy is found, algal biofuels may provide an inexpensive alternative source of fuel that can be produced with little more than sunlight, carbon dioxide, and a small amount of water. While advances in synthetic biology research and the understanding of algal alternatives increases, the scaling up of these fuels requires significant further research resolving the problems of system optimization and photosynthetic efficiency as well as solving ways of producing these synthetic biofuels in quantities suitable for commercial use (Georgianna and Mayfield 2012).

A number of other possible organisms have also been considered as particularly suitable for research into the production of synthetic biofuels. Cyanobacteria are another that initially appears promising. Cyanobacteria, like *Synechocystis* sp. PCC 6803, can provide a highly efficient organic system for producing biofuels as they can convert solar energy and carbon dioxide into biofuel molecules (Wang et al. 2013). Cyanobacteria are particularly good candidates because they possess naturally occurring biosynthetic pathways that produce alkane (a key component of gasoline, diesel, and jet fuel). At present, research into the use of cyanobacteria for synthetic biofuel production is still in the very early stages and well behind that of algae research. However, research focused on reconfiguring these to create an organism that produces alka(e)ne at a rate that is double that of the wild type has been shown to be possible.

Synechocystis mutants have been constructed that overexpress alkane biosynthetic genes. This research demonstrates proof of concept for the potential use of cyanobacteria for biofuel production. If their photosynthetic pathways were reengineered, cyanobacteria may be able to produce alka(e)nes at a highly efficient rate (Wang et al. 2013).

Synthetic biofuel production relying on either cyanobacteria or algae may provide a possible alternative to fossil fuels. The ethical consequences on the environment have primarily focused on how this new technology would (by reducing the reliance on the burning of fossil fuels and anthropogenic climate change) contribute to a cleaner, greener planet. Other ethical impacts concerning the potential negative effects (to not only the environment but also on human health) have been raised by Friends of the Earth (2013). Exposure to synthetic biological materials by lab technicians raises a particular set of concerns that centers on both the kinds of products produced by synthetic biology and their potential risks. The potential for accidental ingestion (e.g., breathing aerosol versions of synthetically produced algae biofuel), the unintended transfer of genetic materials through viral and bacterial elements, the inadvertent contamination or dispersal of nanomaterials and nanoparticles by lab technicians, or the potential escape into the environment of such products has been discussed. These are a concern because of the projectible negative consequences but more so for the unexpected and potentially catastrophic impact on human health (e.g., that ingestion of synthetic materials may lead to disastrous unintentional modifications of the human genome, epigenome, and microbiome) (Hoffman et al. 2013).

Production Problems and Solutions: Tricking Biological Systems to Redirect the Process of Evolution

Although promising, the reengineering of biological pathways to produce high-yield microbial biofuel factories has encountered some formidable obstacles in virtue of their biological basis.

Synthetically engineered organisms, circuits, parts, and systems, like their organic counterparts, have the capacity to adapt to new environments and to evolve over generations. Because these engineered synthetic microbes are biological systems that continue to have the propensity to evolve and mutate, understanding how to design an organism that has predictable behavior is difficult. Their functioning is designed according to the interests of the particular application (e.g., biofuel production) within the lab.

If these built circuits prove cumbersome for the organism once it is in the natural environment, they will be replaced by more evolutionarily suitable pathways. Engineered circuits created in them that do not provide a benefit to the organism may be disposed of in subsequent generations. That is, if producing the high-yield by-products that they are designed to produce does not provide the organism with an evolutionary advantage or increased fecundity, it is likely that this pathway may be lost in subsequent generations. Once a mutation occurs in a later generation that removes part of the biologically taxing pathway responsible for the high-yield production, these mutated organisms may gain an evolutionary advantage over those with the engineered pathway (Kendig 2012, 2013). Over generations, this would eventually lead to a population that would lack the engineered pathway and one where the mutation would be common. As a consequence of this natural selection, the resulting population would produce a lower biofuel yield (Kendig 2012, 2013).

To solve this problem, researchers are currently seeking ways to *trick* the biological system and redirect the process of evolution for the purposes of producing a higher yield product than the organism would produce (Jia et al. 2010). Finessing the organism's circuitry so that it is stable in a variety of environmental conditions and continues to produce high-yield products is of paramount importance. Ethical and environmentally responsible release of an organism that is fully characterized in the controlled context and known parameters of the lab to a new and changing context of the environment requires prior knowledge not only of the organism or circuit's design

and functionality but also its potential mutability and evolvability in an uncontrolled environment.

Ethical Concerns Over the Unpredictability of Potential and Irreversible Impacts on Ecosystems

Evolvability and the co-opting of mutability is not just a production problem; it also opens up a number of ethical considerations. These questions make up a more nuanced set of issues that relate specifically to synthetic biofuel production. Rather than the more often broadly referred to ethical concerns mentioned when discussants claim that this kind of technology should not be advance because it involves scientists “playing God,” these concerns are directly informed through an understanding of the specifics of biofuel research and production. Much of the worry with regard to co-opting of evolvability is the downstream effects or unforeseen consequences of “meddling” with nature.

A frequently used rebuttal to worries that synthetic biologists are “playing God” is the suggestion that farmers have been crossing and breeding livestock, companion breeds of animals, and food crops for a long time and that synbiology is just a technological extension of this. As such, proponents conclude ethical concerns over biologists overreaching in the creation of these synthetically reengineered organisms are thought to be unfounded. The morality of these kinds of synthetic interventions has already been treated to a long and relatively unproblematic beta test in the thousands of years of artificial breeding. Opponents counter that the new technology is dissimilar enough to cause ethical concerns unrelated to that history.

Coalitions such as those that make up the undersigners of the *Principles of oversight for synthetic biology* (2013) – a document of the International Center for Technology Assessment, ETC Group, and Friends of the Earth – have also been instrumental in the initial ethical discussion surrounding synthetic biology research and concerns about the unpredictability of risks and worries over their possible impacts. This coalition

includes civil, social, labor, as well as religious groups concerned with multiple potential impacts that include those economic and environmental.

It raises concerns about the rapidity of scientific research and innovation in synthetic biology without appropriate regulation or consideration of potential risks. They advocate the explicit use of the precautionary principle, specific regulations on synthetic biology, assessment of harm to public health and environment, increased access to synthetic biology research and active participation of public fora, liability and accountability of manufacturers of synthetic biology technology, and increased effort to protect the economic interests of environmentally vulnerable groups and countries (Hoffman et al. 2013).

The undersigners suggest that in order to preclude potential damage that could result from the products of synthetic biology research, “Governmental bodies, international organizations and relevant parties must immediately implement strong precautionary and comprehensive oversight mechanisms enacting, incorporating and internalizing these basic principles. Until that time, there must be a moratorium on the release and commercial use of synthetic organisms and their products to prevent direct or indirect harm to people and the environment” (Hoffman et al. 2013). This moratorium is justified by the coalition because of the potential for long-term harm to the environment. The document suggests that the risks to niche degradation may be long-lasting. For instance, synthetic organisms could be the new super-invasive species crowding out other native species within a particular ecological niche. If synthetic organism parts are highly modular, their genes may lead to the contamination of other species by virtue of their high level of transferability within the environment through horizontal gene transfer.

The Shape of Ethical Discussion So Far

Ethical discussion surrounding synthetic biofuels has come in two sorts so far. The first suggests that the ethical issues that synthetic biology addresses are the same as other emerging technologies and

fundamentally contiguous with those that have been and continue to be discussed. These are the traditional ethical questions of moral behavior, rights and responsibilities, and questions of moral agency. The other suggests that emerging technologies each present fundamentally new sets of ethical issues.

The latter suggests that the resolution to these issues requires consideration not only of the ethical reasoning supplied to us by reading Kant, Aristotle, Bentham, Mill, Anscombe, or Hobbes' approaches to the questions of how should we act or questions concerning what kinds of characteristics are good for someone to have. But they also require engagement with the specific scientific research and technology itself in order to fully inform ethical reasoning. Both are required to answer questions such as the following: What are the limits of human intervention within the natural world? Should we intervene and co-opt the selective processes of evolution and bend these to our will? How should we behave as researchers? What responsibilities do we have for the society, the environment, and for the unintended effects of the new technology created? Who owns the products of these types of research or the rights to use the technology once patented?

Insofar as synthetic biology is a relatively new form of scientific research and the applications to biofuel in their early stages, ethical discussion surrounding these is still in the investigative stages of development relying on panoply of reference points to gain traction on new ethical questions.

The ethical discussions of synthetic biology research in general and the application to produce biofuels in particular have progressed along very different routes to that of the discussions surrounding genetically modified foods. The most striking difference has come in the public perception of this new technology and the encouraged exchange between research bodies and the public in open forums. Commissions and research units such as the aforementioned US Presidential Commission for the Study of Bioethical Issues, the Hastings Center Ethical Issues in Synthetic Biology project (launched in 2009 and funded by the Alfred P. Sloan Foundation), and the

SYNBIOSAFE consortium (set up in 2007 and funded by the European Commission) have promoted scientifically informed ethical discussions that bring together key researchers, policy makers, academics, and the public with the goal that through dialogue there can be increased understanding and appropriate regulation of this new biotechnology in a way that is responsive to the interests of scientific innovation and public concern.

In doing so, these cross-disciplinary bodies aim to focus less on the speculative ethical debates of the potential problematic products or misuses of synthetic biology research. Instead, their foci are on current research problems and issues with practical applications in the not-too-distant future. Open debates which inform the public about current research, objectives, and technological applications rather than spurious conjecturing based on worries derived from science fiction and hypothetical slippery slope arguments have been the goal of these commissions and consortia.

Towards Scientifically Informed Ethical Discussion

The promise of a cheaper, greener alternative to fossil fuels is an attractive application of synthetic biology research. But with the capability to construct organisms for this and other applications comes a veritable flotilla of ethical considerations. Including those already discussed in the foregoing, these concern each stage of development, from research and design to the production, use, regulation, impacts on the environment, modes of release and dissemination, public perception, and marketing.

In response to the J. Craig Venter Institute's 2010 announcement that they had created "synthetic life" by digitally crafting DNA and inserting it into a living bacterium to produce a new self-replicating bacterium, *Mycoplasma mycoides* JCVI-syn1.0, the US Presidential Commission for the Study of Bioethical Issues produced the report, *New Directions: The Ethics of Synthetic Biology and Emerging Technologies*. This report provided guidance and consideration of policies,

governance, and practices that would enable synthetic biology research and applications of it to be pursued in an “ethically responsible manner” but did not endorse further federal regulations on synthetic biology research (Presidential Commission for the Study of Bioethical Issues 2010). In doing so, the Presidential Commission followed the recommendations already laid out by the Engineering and Physical Sciences Research Council, the Biotechnology and Biological Sciences Research Council, the Economic and Social Research Council, and the Arts and Humanities Research Council of the United Kingdom (Anderson et al. 2012).

In the *New Directions* report, the Presidential Commission set out five principles to guide discussion of the ethical and social impacts of synthetic biology research and technological applications. The report’s recommendations are framed in terms of these five principles. These are as follows: intellectual freedom, democratic deliberation, responsible stewardship, and considerations of justice and fairness. With intellectual freedom, responsibility for the implications of synthetic biology research and technological applications is put largely in the hands of the researchers to self-regulate rather than promoting a top-down approach for regulating practice. The US and UK initiatives stress prudence and responsiveness with regard to the emerging area of research still in its infancy.

Crucial issues mentioned within the US report focus on responsible stewardship to the world and its occupants, including considerations of non-human animals, plants, and future generations, as well as the environment as a whole. Consideration of these groups within the context of a discussion of obligations is not new. Although not cited, the report’s main ethical foci seem to rely significantly on philosophical ideas similar to those laid out in 1990 by Edith Brown Weiss in her seminal article, “Our Rights and Obligations to Future Generations for the Environment.” To summarize, Weiss suggests that the rights of each generation are to receive the planet in no worse condition than did the generation that came before it. This would mean that each generation should inherit comparable natural diversity and have

similar access to the environment and its resources as did the previous generation. She suggests that rights and obligations do not arise *de novo*, but instead derive from an intergenerational relationship that each generation shares with those in the one preceding it as well as those in the subsequent generation yet to come (Weiss 1990).

Summary

Scarcity of resources and the unsustainability of the continued use of fossil fuels drive the synthetic biological engineering of biofuels. The initial sources of biofuels based on collecting and fermenting the biomass of food crops (such as corn) proved highly controversial. The growth of corn ethanol producers and the increase in food shortage attributed to the subsequent worldwide backlash and contributed to much critical discussion. These first-generation biofuel discussions concentrated on the ethical impacts of agricultural land use for biofuel crops and limited water supplies previously used to produce food that were now being used to produce fuel instead.

Despite the problems with first-generation biofuels, investment in second-generation synthetic biofuels by private companies as well as government support of research (especially in the United States) has been significant (Tyner et al. 2011). If the demand and pursuit of liquid transportation fuels continues, synthetically reengineered alternatives which provide functional equivalents to fossil fuels may be the greenest option as they may offer a more renewable avenue to the production of fuel.

Although synthetic biofuel production shows much promise as an alternative energy source that does not require the use of non-sustainable feedstocks or expensive carbon sources, its ability to replace fossil fuel consumption rests on developing the technology to produce it economically while reducing any negative environmental impacts. Despite their overuse, contribution to anthropogenic climate change, and the source of frequent international disputes, the replacement of fossil fuels will still rely overwhelmingly on

economic production of an efficient, high-yield alternative source of energy (Georgianna and Mayfield 2012).

As synthetic biology is still a new field of research and only some of the potential applications are just being realized, open discussion with scientists, policy makers, and the public may provide the best prospects according to many commissions and consortia in the United States and United Kingdom. Discussion of the actual scientific research and its accurate dissemination to media and the public would allow productive and democratic exchanges of a well-informed public and a responsive scientific community collaborating to evaluate the direction of new research. The goal is for these discussions to stimulate active enlightened deliberation directed towards navigating the best route (s) for ensuring the pursuit of this research, critical evaluation of its potential positive and negative impacts.

Synthetic Meat

David B. Dillard-Wright

Department of History, Political Science and
Philosophy, University of South Carolina Aiken,
Aiken, SC, USA

Synonyms

Cultured meat; Hydroponic meat; In vitro meat;
Shmeat; Test-tube meat; Victimless meat

Introduction

The goal of creating viable synthetic meat in the laboratory and eventually in the factory has been driven by economic, environmental, and ethical concerns about the current state of animal agriculture. Livestock production ranks as one of the leading causes of deforestation, global warming, pollution, and water depletion, problems that will be exacerbated as the expanding middle classes in countries like China and India demand a Western-style, meat-heavy diet. The United Nations Food and Agricultural Organization estimates that “Global production of meat is projected to more than double from 229 million tons in 1999/01 to 465 million tons in 2050” and that the “environmental impact per unit of livestock production must be cut by half, just to avoid increasing the level of damage beyond its present level” (UNFAO 2006).

This technology, currently in its infancy with, as yet, no viable commercial product, takes animal fat and protein cells grown on a collagen scaffold in a nutrient medium and then shapes the cells into a product resembling its predecessor in conventional agriculture. Most likely, hamburgers and nuggets would be lab grown long before steak, since growing complete muscle tissue, with its complex network of membranes and filaments, would require a three-dimensional architecture and not just a single layer of cells. Advocates suggest that animal welfare and environmental considerations would be addressed

using this process and that nutritional value could also be improved, since the composition of synthetic meat could be completely predetermined. A number of obstacles must be addressed before laboratory-based meat reaches the grocery store: the procedures must be perfected and brought up to scale, and the public must be reassured that synthetic meat is every bit as “real” as meat grown on an animal.

History and Technique

Winston Churchill first wrote about lab-grown meat in his 1932 book, *Thoughts and Adventures*, musing that it would be much more efficient to simply grow a chicken breast rather than a whole chicken. Churchill had probably heard of Alexis Carrell at the Rockefeller Institute, who kept a piece of chicken heart tissue alive in the laboratory for 20 years (Levine 2008). Cultured meat has appeared in a number of science fiction novels, including Frederik Pohl and C.M. Kornbluth’s *The Space Merchants* (1952), William Gibson’s *Neuromancer* (1984), and Margaret Atwood’s *Oryx and Crake* (2003). While never reaching the widespread use depicted in novels, the technology needed to produce meat in the laboratory continued to advance throughout the twentieth century.

In vitro techniques have been a standard part of laboratory-based science since 1907, when Ross Harrison cultivated frog nerve cells in a lymph medium at Johns Hopkins University (Corning Life Sciences 2007). Since then, many practical and research applications for the much-improved technique have been discovered, including investigating the normal growth and development of cells, testing new drugs and products for toxicity and effectiveness, producing biological factors like proteins for therapeutic use, and growing tissues for treatment of wounds and diseases (Chaudry 2011). The chief difference between earlier forms of cell tissue and the technology needed for laboratory-based meat is the sheer scale necessary to produce food from this procedure, although industrial levels of biological compounds have been created in the past, as in the

polio vaccine of the 1950s and its other vaccine successors.

Notable attempts have already been made to take in vitro cultivation of cells into the domain of food production. The first patent on in vitro meat for human consumption was recorded by the European Patent Office in 1999 on behalf of three citizens from the Netherlands. Several experiments have taken place to make the technology viable. Morris Benjaminson at Touro College in New York experimented with growing goldfish fillets in research funded by NASA, with the hope that eventually astronauts could grow their own food in space without the need for processing animal excrement in addition to human waste (Sample 2002). Benjaminson took strips of flesh from very large goldfish and kept them in a serum derived from fetal cows and successfully coaxed the strips of muscle into growth (Sample 2002). Benjaminson dreams of a day when countertop bioreactors, “like a coffee maker,” will produce meat for consumers right in the home (McIlroy 2006).

Research conducted by Mark Post at Maastricht University in the Netherlands uses muscle stem cells in the hope that one day an artificial hamburger could be created by blending these cultured muscle cells with cultured fat cells. The already differentiated muscle stem cells, which repair muscle damage in a normal organism, do not reproduce indefinitely, so new cells (harvested from living animals) would need to be added continually to make the procedure work commercially (Krijnen 2012). After some problems initially with the pale color of the experimental product, Post held the first public taste test of a lab-grown hamburger in August of 2013.

Now that the concept of lab-grown meat has been proven in labs, future generations of researchers will need to build the technology on a larger scale, ensure that the appearance and flavor of the product meet consumer demand, and find partnerships with companies and investors to bring the product to market. Especially important will be the development of serum-free techniques, as the existing fetal bovine serum presents concerns about animal ethics as well as cost. The serum substitute Ultrosor G, although also

costly, has shown some promise in research trials: a mushroom-based growing medium could theoretically be developed as a low-cost alternative (Dattar and Betti 2010).

A Potential Solution to Inefficiency

Confined Animal Feedlot Operations (CAFOs) and even more traditional grazing practices have a low rate of conversion from silage or feed to the eventual meat that makes it to the dining table. Although estimates vary widely, “beef” has an approximately 8:1 feed ratio, taking 8 lb of feed to produce 1 lb of flesh, with “pork” more efficient at a 3:1 feed ratio, and chicken and fish falling in line at about 2:1. The eventual cost to producers will change from season to season with the cost of grain, the cost of petroleum, and prevailing interest rates. Factors like nutritional balance, air temperatures, and daily exercise also affect the amount of food necessary to produce meat. Traditional agricultural practices like rotational grazing reduce the need for processed and transported food, but such practices constitute a small minority of the meat that goes to market. Even lacking humane and environmental factors, meat producers have economic incentives to increase the bulk of the animal with a lower amount of feed.

Lab-produced meat advocates suggest that an in vitro life form, devoid of the need for locomotion and sensation, would “waste” less energy compared to traditional farm animals. Sewage lagoons and other manure management problems created by intensive livestock farming would be eliminated, and with them methane pollution, a large contributor to global warming. Experts project that the process of growing lab-based meat would be faster than the time required to bring a living animal to maturity at the time of slaughter, and because such facilities could be stacked vertically, land use would also be reduced (Dattar and Betti 2010).

By growing only muscle and fat cells necessary to produce a reasonable simulacrum of the meat-based products that consumers want, the amount of inputs (such as water and nutrients) needed to produce in vitro meat would be reduced.

Animal agriculture has already industrialized to a great degree, and lab-produced meat continues this process even further by shifting from an animal with biological habits to industrial tissues that can be readily tailored to the needs of the factory. The labor-intensive and comparatively slow process of slaughter and dismemberment can be eliminated altogether in favor of a completely streamlined production of “steaks,” “nuggets,” and “cutlets” that resemble and taste like their predecessors in the old agriculture. Transportation costs would be reduced by bringing the growth process to the same physical location as production and packaging, eliminating the need for the shipment of live animals. Nutrient material would presumably still need to be shipped, but savings could be enacted by bringing in vitro facilities closer to grain producers who would presumably still be needed to produce the nutrient bath needed by the in vitro life form.

Reduction of Animal Suffering

Proponents of artificial meat consider it to be a “victimless,” harm-free form of agriculture (McHugh 2010). Indeed, People for the Ethical Treatment of Animals (PETA) has offered a one million dollar reward to the first lab that can produce a “real artificial” chicken nugget (PETA 2012; McHugh 2010). It should be noted that in vitro procedures are not and probably will never be fully free from ties to living animals, as the stem cells used in the process, which have already differentiated into tissue types, must be harvested from somewhere. The techniques also use serum derived from living animals in order to instruct the cultured cells to replicate. To date, lab-based meat experiments actually amount to animal-intensive undertakings. The perfection of the technology may reduce this dependency but will probably not sever all ties to traditional, living organisms. PETA support notwithstanding, many vegan animal advocates will not accept the claims of lab-produced meat as “harm-free.”

Vegan and vegetarian critics of animal agriculture insist that feeding something already edible to animals constitutes an inherently wasteful

practice that should be eliminated. Food crops like corn and soybeans could be fed directly to humans, resulting in much less waste than converting foodstuffs into meat. The cultural habit of meat eating dies hard, however, and many animal advocates would be willing to accept lab-grown meat as a way of transitioning long-term meat eaters away from conventionally grown meat products. Lab-grown meat would likely result in the continued use of animals in its production, but nowhere near the number of animals killed in current agricultural practices. Ethical arguments about animal suffering are intrinsically linked to the above-mentioned questions of efficiency, as the increased efficiency of lab-grown meat would reduce the need for industrial farming.

Containment of Disease and Reduced Use of Antibiotics

Unlike conventional animal agriculture, in vitro meat could be grown in a sterile environment, reducing the risk of animal-borne pathogens and removing the need for antibiotics (Dattar and Betti 2010). Food scares like the outbreaks of bovine spongiform encephalopathy (BSE, popularly known as mad cow disease) and instances of *E. coli* contamination have raised concerns about the safety risks of today’s food systems, which tend to aggregate plant and animal foods from many different points of origin, increasing the risk of cross-contamination (Jin et al. 2004; Centers for Disease Control and Prevention 2012). Lab-grown meat could be cultivated, processed, packaged, and sealed at the point of origin, significantly reducing the potential for the spread of disease.

Animal agriculture currently accounts for upwards of 70% of all antibiotic use, which contributes to the development of antibiotic-resistant strains of bacteria (Hielig et al. 2002). Although the exact amount of “epidemiologic ‘spillover’” from farms to humans of resistant strains is uncertain, “there is no question that the phenomenon does exist” (Hielig et al. 2002). Such heavy antibiotic use stems from feeding cattle – ordinarily

ruminants – corn and soybeans that they cannot digest easily, resulting in ulceration and infection that must be treated. The stress of crowded and unsanitary confinement also renders animals more susceptible to illness. Antibiotic use makes meat production more profitable, but it has a tremendous negative impact on public health (Hielig et al. 2002). Doctors and researchers must continually search for new drugs as bacteria become more and more resistant to the existing antibiotics.

Nutrition and Obstacles to Public Acceptance

A study published in the *Archives of Internal Medicine*, combining the results of two previous studies with over 100,000 subjects followed over decades, reported an increase in mortality from cancer and cardiovascular disease (as well as an increase in overall deaths) as a result of consuming red meat (Pan et al. 2012). Risk of mortality was slightly higher across categories for processed meat than for unprocessed meat (Pan et al. 2012). The study reported that 9.3% of deaths in men and 7.6% deaths of women in these cohort groups could be prevented if red meat consumption were kept below 0.5 servings per day (Pan et al. 2012).

Parsing the exact implications of this study for synthetic meat would require additional research, specifically, an isolation of the detrimental nutritional aspects of conventional meat and a comparative nutritional study of traditional and synthetic meat. Lab-grown meat could, in principle, be manufactured according to any nutritional profile, but nutrition would need to be matched against the desired flavor and appearance to meet consumer demand. Reducing fat content, for example, would make the final product tougher and less palatable, particularly for North Americans and Europeans, who have grown accustomed to corn-fed beef and pork.

If the public could be sold on the benefits of lab-grown meat in terms of its nutritional and ethical value (by no means a foregone conclusion), the question would still remain as to the “ick” factor of in vitro meat. Genetically modified

foods still spark a great deal of controversy, even though consumers have to date largely lost the fight for labeling requirements. “For more than a decade, almost all processed foods in the United States” have contained ingredients from genetically modified plants (Harmon and Pollack 2012), a fact quietly lost on most shoppers. It could be that the inevitable fight over synthetic meat would proceed initially with a great deal of bluster followed by the same grudging acceptance. Most likely, lab-grown meat would exist alongside traditional meat and plant-based meat substitutes as a new niche in the marketplace.

The question remains as to whether this small segment of the market would be large enough to get the economics of artificial meat to work well enough to sustain production. Consumers have had decades to adjust to vegetable-based meat substitutes, and the available products have improved greatly in taste and texture. Meat substitutes from companies like Morningstar Farms and Gardein have enjoyed increased popularity and appear in the freezer sections of most grocery stores, although unfamiliarity with the products as well as concerns over taste and texture continue to keep meat eaters away (Hoek et al. 2011). Ethical and environmental arguments do not appear to sway meat eaters to try vegetable-based fake meat, and researchers contend that improved taste would be more likely to do the trick (Hoek et al. 2011).

If lab-grown meat approximated the taste of traditional meat no better than plant-based meat substitutes, it seems unlikely to succeed in the marketplace. To overcome consumer reluctance about the newness of the product, it would have to taste virtually identical to traditional meat and compete in price, taste, and appearance with plant-based meat substitutes. These hurdles will be very high, though not impossible, to overcome, although it may take years if not decades for this to happen.

Beyond questions of taste, cultural practices around food and the common table also stand in the way of an acceptance of lab-produced meat. The home and hearth are identified with the organic and the natural and a pastoral ideal that may not reflect the reality of today’s factory

farming. The idea of producing meat in a sterile facility further removes food from the landscape in a way that many consumers would find unsettling. The nature/culture divide may not exist in an absolute sense, but it still informs the way that people think about food. Wholesomeness of food products is tied to an imaginary sense of naturalness very much related to the family farms of the early twentieth century. Lab-produced meat has some very high, though not insurmountable, cultural barriers to be overcome. Since the public has accepted the industrialization of meat production, the transition to lab-grown meat can be viewed as the next logical step in this process.

Summary

Lab-grown meat has numerous potential advantages over the current practices of large-scale animal agriculture. Environmental problems like deforestation and pollution could be mitigated by a switch to synthetic meat, and the new technology has the potential to alleviate, though perhaps not eliminate, animal suffering. Additional benefits include lower risk of animal-borne disease and a more nutritious product. The current state of the technology relies on the cultivation of muscle cells in a collagen matrix, using fetal bovine serum as a nutrient bath. If in vitro meat is to become a mainstay, the technology must be scaled upward to produce consumer quantities at a lower cost. Many objections will have to be addressed, including remaining doubts about animal welfare, the perceived unnaturalness of the product, and anxieties about the newness and difference of lab-based food.

Systemic Ethics to Support Wellbeing

Co-determination; Interconnectedness; Inter-dependency; Interrelatedness

Introduction

This section makes the case for systemic ethics to guide a new form of democracy and governance to protect the common good and the global commons, based on recognition that caretaking for well-being is “an idea whose time has come” (<http://www.health.govt.nz/publication/idea-whose-time-has-come-new-opportunities-health-impact-assessment-new-zealand-public-policy>).

The axiom on which systemic ethics for caretaking is based is that we can be free and diverse to the

extent that our freedom and diversity does not undermine the rights of others or future generations of life. This section provides an overview of systemic ethics, based on considering the consequences of our thinking and practice for ourselves, others, and the environment. It sums up research on systemic thinking and practice (praxis) on reframing sociocultural values imbedded in not only democratic rights but also democratic responsibilities to others (including the voiceless and sentient beings), the environment, and future generations.

Caring stewardship is a process resulting from thinking and practice based on an understanding that what we do to others and to the environment, we do to ourselves and to our children. The land is placed first by First Nations internationally (Rose 1996). Post-colonialism and Indigenous knowing is important in understanding what stewardship entails for our relationships with others, the environment, and the next generation of life. Systemic ethics underpins the case that citizenship rights need to be scaled up to enable people to think in terms of the global commons on which we *all* depend for our survival. Contractual rights – as defined by the social contract between the citizens and the nation-state – do not go far enough to protect common needs, nor does the social contract protect the global commons (which includes air, water, soil, and the genetic code of life). The understanding of who we are and how we relate to one another is a starting point for exploring “our identity as caretakers.”

Recognition of Our Dependency on the Land

The environment affects people through the quality of the air they breathe, water supplies, and agriculture, and people in turn affect the environment through the way they think and practice. The way we think and practice has ethical implications for the way in which this generation uses the planet's resources and has implications for future generations of life (see Hulme 2010). We have all heard the expression “Less is more” as applied to unpretentious good taste – rather than poor taste based on ostentatious extravagance and greed

which leads to impoverishment – and in all probability life as we know it.

The Ministry of Environmental Affairs and Tourism, South Africa (2004, p. 41), cites Rosenberg:

current patterns of consumption by 20% of the world's richest people indicate that they consume 45% of the meat and fish, own 87% of the cars, use 84% of paper and 75% of all energy resources. . . . They also generate 75% of the annual global pollution.

Different interest groups have different perceptions, emotions, and values about the consumption and the nature of property and power to make decisions ranging from neo-Marxist arguments developed by Noam Chomsky(2005) and John Pilger (2002) about new forms of colonialism to arguments about the crisis and collapse of capitalism, to social democratic arguments about the reform of the market (Held 2004; Wilkinson and Pickett 2009), and to green democratic arguments about the way people can mobilize change (Dryzek 2010) and Indigenous standpoints (Atkinson 2002) on the long-term implications of inequity and greed –some of which have been taken up by communitarian (Etzioni 2004) views on global stewardship and, most importantly, critical reframing (Hulme 2009, 2011; Beck 1997).

Where one places oneself on the continuum of values has implications for the **governance** of people and resources based on the way property and consumption are defined and for the **inclusion** of the marginalized in policy decisions. Furthermore, Urry (2007) highlights the implications of living in a world where the majority are urban based and reliant on the carbon economy for cooling and the transport of their food to the city:

. . . the world went urban on 23 May, 2007, this being 'transition day', when the world's urban population exceeded the rural for the first time. One consequence is that the proportion of the world's population that are poor is inexorably rising, with the proliferation of massive 'global slums' . . . (Urry 2007, p. 197)

Urry raises the prospect of 'failed city states:

unable to cope with oil shortages and the droughts, heat waves, extreme weather events, flooding, desertification and so on. Their instabilities spread across

borders, affecting neighbouring regimes through forced migrations, weakened public health and degraded conditions of life. (Paskal 2007; Urry 2010, p. 197)

The Sydney Peace prize winner Vandana Shiva sums up the challenge for this century as one of preventing the commodification of life (see <http://www.youtube.com/watch?v=UOfM7QD7-kk>, <http://www.navdanya.org/news/229-awesome>, <http://www.vandanashiva.org/>).

Multinational companies and the WTO have made it possible to patent the conditions of life, thereby causing almost a quarter of a million suicides by Indian farmers who cannot afford to purchase the seeds and the pesticides that are needed (despite the claims by the manufacturers). Furthermore, the attempt to criminalize farmers who store old varieties of seed could lead to very vulnerable food monocultures. The idea that the very basis for life – seeds and genes – can be patented is part of the process of commodifying people, animals, and the fabric of life.

Crish and Fayne (2010) stress the costs of declining agriculture which are felt by women and children in the cities. Most of whom survive through social support networks and informal trading – estimated to be 500,000 traders in SA (2010, p. 12) and 70% are women. They cite the International Labour Organization (2003): *Street Traders and Their Organization*. According to the latter, extreme poverty, prostitution, and AIDS are the result of food insecurity, and children have less protein and less micronutrients – iron, iodine, and vitamins.

Agricultural production has contracted in South Africa.

"Life expectancy actually declined over the past 40 years in . . . six states in . . . sub-Saharan Africa: the Democratic Republic of the Congo, Lesotho, South Africa, Swaziland, Zambia and Zimbabwe." 40-year Trends Analysis Shows Poor Countries Making Faster Development Gains. UNDP 4 November 2010 <http://hdr.undp.org/en/reports/global/hdr2010/news/title,21577,en.html>. Accessed 2 February 2011.

In South Africa, Crish and Fayne (2010) argue that cash, not rural, agriculture is the way in which the majority feed themselves in South Africa. For example, "in 2000 only 5% of all South African

households used agriculture to supplement household food. . .” By 2020, the urban populations of less developed countries will exceed rural populations and continue to climb – three billion more will soon be in the cities of the developing world. Food can be the single largest expense in households – 39% of the average household expenses. Internationally, the global financial crisis combined with the effects of climate change will lead to higher levels of starvation. In South Africa alone, farming jobs have contracted from one million workers in 1993 to approximately 660,000 workers at the end of 2010. The nongovernmental organization coalition found that “life is getting harder for the rural poor” and that female-headed households are amongst the poorest. Stunting and infant mortality have “risen from 48 to 54 per thousand for Africans,” while “for whites it fell from 7.4 to 7.3 per thousand.”

Ethically, the focus ought not to be merely on poverty and food security, but instead on the extreme wealth of *some* which contrasts with the underfed and the starving two thirds of the world’s population. Overconsumption and obesity are a result of *both* life choices and life chances. The link between obesity and capitalism is clearly the result of resource- or time-poor people who do minimal exercise and rely on fast food.

The challenge for developed and developing nations is to achieve or maintain:

- Access to safe housing (including energy and water), appropriate education, and employment to enable social and environmental justice; but within
- Livable cities that are in turn supported by
- Sustainable regions that support agriculture, animal husbandry, forestry, and fishing.

The impacts of climate change (and possible actions to minimize the impacts) present a complex problem to communities and governments around the world. The challenges facing the most marginalized in the community are challenges that could be suffered more widely as the impact of systemically linked social, economic, and environmental challenges leads to accelerated changes to the livability of cities and regions on

which they depend. Climate change will affect the standard of living that is taken for granted by the privileged (Fiona Stanley, Hawke Oration lecture 17 November 2008).

Stewardship philosophy needs to be reapplied (see Ottawa Health charter 1986, <http://www.who.int/healthpromotion/conferences/previous/ottawa/en/>; Bruntland Report 1987, <http://www.un-documents.net/wced-ocf.htm>).

The social contract protects citizens within the nation-state, but those who do not vote (young people and the disabled) rely on the care of others. Those who fall outside the mantle of the nation-state remain without protection. In more equal societies, people consume less and are less status conscious. Some scholars (Dryzek 2010) propose that not achieving those simultaneous aims affects human rights and the groundswell of democracy that seeks to limit the effects of climate change through social and environmental justice. The Club of Rome research needs to be extended to *engage with global citizens*, which is perhaps one of the reasons it did not gain traction. Participants need to consider issues in terms of expanded pragmatism (namely, the consequences for their own children) which could have helped people develop *the will* to make changes in their own lives and to lobby for environmental issues. People need to want and demand “the impossible” (http://www.salon.com/2011/10/24/judith_butler_at_occupy_wall_street/), namely, affordable food and responsible state-market and civil society coalitions.

The Capabilities Approach Guides Systemic Ethics

Systemic ethics (McIntyre-Mills 2010) is based on understanding the social, economic, and environmental consequences of:

- The **extreme luxury** enjoyed by the few is at the expense of the majority *in this generation* (Davies and World Institute 2008) and at the expense of the next generation.
- The **zero-sum approach** of “us/them” thinking leads to shifting responsibility and blame for resource use and resource management.

- The **denial of the links** across the social and environmental system in relation to the consumption of energy through wasteful living. We need to move beyond debate couched in mutually exclusive narratives and recognize that we can be free and diverse to the extent that our freedom and diversity does not undermine the rights of others or the next generation of life. The limits to diversity are set by our dependency on the land of which we are part.

The threefold aim of systemic ethics is to make a case for:

- Processes and structures that *enable regional, transnational* democratic dialogue on difficult issues of social justice and sustainability
- Enabling participants to consider the consequences of socioeconomic decisions for this generation of life and the next
- Controlling rights so they cannot override responsibilities to save resources for the next generation

The test for the moral law is being prepared to live with decisions if they were to be applied to oneself and one's own children. This is the basis of social contractualism developed by John Rawls (1999) who explains in "The Law of Peoples" that this "veil of ignorance" approach is the basis for liberal democracy. The problem is that the social contract is too limited to take into account the needs of the powerless, such as the disabled, children, and animals. Compartmentalized thinking undermines accountability and risk management.

'A priori' means ethics based on the moral law and a sense of duty – irrespective of the consequences. Traditionally, idealism and Kantian ethics is considered to be focused on the duty of human beings. In this section, a case is made for duty – based on considering the consequences of decisions for this generation and the next. Kant's "moral law" focused on human beings. The humanist idea of respect (based on treating people as ends in themselves and not as a means to an end) has been translated into practice in limited ways.

A case needs to be made for extending the social contract, because it is inadequate to protect the environment. Furthermore, it does not address the interests of citizens who are young, disabled, or members of other species (Nussbaum 2006). The contract is not extended to noncitizens. By focusing on the future generation of life, we can extend our time frame and our sense of solidarity. Without power, the potential remains for people to be silenced or treated as commodities. Controlling consumption requires changing bad habits which in turn requires the political will to transform praxis. This has implications for transforming governance and democracy to ensure that the market is not allowed to destroy the life chances of the many for the benefit of the few.

Emergence is the ability to escape the trap of our own thinking, to cite Vickers (in Beer 1974, p. 252): "the trap is a function of the nature of the trapped." According to his theory of "recursive consciousness," we are able to emerge from our entrapment through making connections and realizing that we have the capability to achieve transcendence as we become more conscious.

Consideration of the question "how should we live?" ought to be guided by considering the consequences – not only for our own life, but the consequences for our neighbors and future generations of life. What we decide, how we decide, and who we decide to include in a conversation need to be guided by careful questioning and respectful dialogue. Hulme (2011) characterizes a single focus narrative as reductionist and stresses that we need to be aware of different narratives on climate change, in order to enhance our resilience and our ability to think about our thinking.

The capabilities approach takes its start from the Aristotelian/Marxian conception of the human being as a social and political being, who finds fulfillment in relations with others (Nussbaum 2006, p. 85).

Rose (1996, 2004) argues that a first step towards building our capability is to understand our role as caretakers. This requires recognizing the colonial mindset without adopting a naïve approach that one culture has all the answers. The challenge is to understand that "we are the

land” – and that measuring a carbon footprint is merely a response to the problems we have created through extraction of surplus from the land and labor. The economic bottom line of profit needs to be replaced with well-being, based on systemic ethics, rooted in respect for personal and planetary well-being. We deny that “we are the land” and that – along with all life – we return to the elements of life when we die. We become the ancestors and nurture the land from which new life grows. Caretaking can also be assisted by the so-called Tuvalu test developed by physicists (Murray et al. 2007) which helps policymakers understand that human beings are systemically interconnected and dependent on the environment. It provides a step towards appreciating social, economic, and environmental accounting and accountability to others. The test suggests that we need to consider how our carbon choices make a difference to others. Carbon choices made in developed nations impact on rising sea levels, for example, that impact on agriculture and food security.

Systemic ethics addresses emotions, values, and perceptions when making decisions, because emotions are one of the building blocks of consciousness (Greenfield 2000). To be able to address complex wicked problems, we need to address values and emotions. Scenarios, narratives, and art can be used to help us explore complexity and our emotions. Ethical literacy can be assisted by asking questions, in order to draw on many kinds of knowledge (see McIntyre-Mills 2010, drawing on and adapting West Churchman 1979), and striving to match areas of concern to areas of knowledge that will enhance well-being by considering the following:

- Subjective ideas that are brought into intersubjective processes.
- Logical relationships across ideas.
- Empirical data for the big (broad) and small (detailed) picture.
- Idealism (not thinking about the consequences), because the moral law states we need to treat people as ends in themselves and not a means to an end and the capabilities of sentient beings (Nussbaum 2006).
- Intersubjectivity, based on compassion, care for the voiceless, and meaningful communication with those who can engage in dialectical relationships that explore one argument versus another argument and then cocreate shared meanings within context.
- Caretaking considerations are based on considering the consequences for this generation of life and the next which leads to the best integrated response drawn from diverse ideas.

As human animals, we have evolved as *Homo sapiens sapiens*. Human beings are the so-called ‘twice wise’ who are ‘capable of thinking about our thinking’ (Banathy 2000). We human beings are the designers – for better or worse. But our appreciation that we are co-determined by the environment no longer guides (our) designs. This also has implications for policy designs that take into account regional considerations and our systemic interconnectedness. Indigenous peoples the world over have expressed a spiritual connection with the environment based on both fear and reverence. Systemic ethics is rooted in an appreciation of our dependency on nature and recognition of Indigenous wisdom, based on an understanding of the notion of caring for the land. Culture, design, and tools must be used to adapt to the environment. Today, the human species tries to adapt the environment to the so-called needs of a deified, reified market. This is unsustainable. Instead, we must use our creativity to protect the land.

Research into participatory governance for social and environmental justice is based on testing out ideas and considering “if-then” scenarios to enhance the capability of people to think about the consequences of their decisions for others and the next generation of life. “If-then” scenarios need to take into account the social, cultural, political, economic, and environmental dimensions of an issue.

The ‘**enemies within**’ refers to human values, namely, religion, morality, politics, and aesthetics (West Churchman 1979) that filter our understanding of the world and that affect our emotional understanding of the world. Ethical decisions need to avoid polarizing *emotion* versus *reason*

and to accept that emotions have played an important role in enabling cooperation and communication across the evolutionary continuum. This requires the ability to ask questions and consider ‘if then’ scenarios (see Ulrich 1983). Greenfield (2000, p. 21) argues that emotions and feelings are the most basic aspects of consciousness. She calls them “the building blocks,” and when we temper our emotions through thinking through implications of “acting out” passions, we are able to become more mindful or conscious. Emotions can limit our consciousness, but they can also alert us to issues that we need to think about. Passion and compassion are the flip sides of one another. The more connections we can make, the better our thinking, our policy processes, and our governance outcomes will be. Nussbaum defines quality of life and development in terms of ideals, and she recognizes the emotional dimension of ethical thinking in both personal and public lives.

A new form of green democracy and governance needs to be designed which takes into account both (a) a priori and (b) a posteriori approaches to promote systemic ethical stewardship (see an example of praxis to reduce consumption by the privileged living in the urban environment; click here for access to the video (<http://www.dropbox.com/sh/q5750v9ilibnok/zEcunDKP6R>)).

Both increased equality and increased control could make a difference. The former requires the will to make policy that supports both democracy and sustainability. This requires ethical decisions based on both a priori and a posteriori ethics. Norms need to be institutionalized through governance.

The problem of engaging large groups of diverse interest groups is threefold. The tendency to think in *linear, systematic* terms is exacerbated by an attempt to summarize ideas, rather than exploring and engaging with people to enable them to think about their values and about the interconnected consequences of their choices (Hulme 2009; Vickers 1983).

Stiglitz et al. (2010), the past vice president of the World Bank, along with his colleagues have stressed the systemic nature of social, economic, and environmental challenges. Stiglitz et al.

(2011, p. 15) use a multidimensional measure of well-being spanning:

1. Material living standards (income, consumption, and wealth)
2. Health
3. Education
4. Personal activities including work
5. Political voice and governance
6. Social connections and relationships
7. Environment (present and future conditions)
8. Insecurity of an economy as well as a physical nature

Stiglitz has stressed (at the invitation of the Australian Productivity Commission) that the bottom line is well-being – this requires building *stocks for the future* (Stiglitz et al. 2010) to protect the basis of life.

Biospheres are regions which are currently protected by the United Nations; they have the potential to be scaled up as overlapping regions. Current forms of engagement on sustainability issues involving large groups of diverse stakeholders have failed. This is evident from the failed United Nations Copenhagen Summit (COP 15) and at the Cancun Conference in 2010 (COP 16) which were unable to draw on the “wisdom of the people” (Christakis 2004) or to achieve significant governance controls. Dahl’s (1967) pessimism about choosing nested systems of governance – because democracy was designed for the city-state – has long been overturned by the necessity to develop an understanding of our interconnectedness across many cities and that the cities are dependent upon the land. The Copenhagen Summit (2009), Cancun (2010), and Durban (2011) remain a continuing source of inconclusive discussion. It demonstrates the need to develop a means to enable large groups of people to explore the implications of complex challenges such as poverty, climate change, and competition for resources and then to reach sustainable decisions. The Copenhagen Climate Change Summit illustrates that even when organizations try to include diverse stakeholders and diverse viewpoints, the challenge remains as to how to include diverse viewpoints.

The aim of ethical governance is to find a way to manage consumption through reducing the size of the carbon footprint of businesses, government, and domestic users, as reflected in governance codes that reward living in a sustainable way in each local council area. The next decade requires decisive socioeconomic intervention (Stern 2006, 2009; Lovelock 2009) to discover the processes and governance structures that enable social justice and sustainability, in order to reduce consumption and thus to enhance social and environmental resilience.

Systemic Ethics for Caretaking

Systemic ethics for caretaking requires developing the capability to think through the consequences of decisions for the long term within and beyond the boundaries of the nation-state. It requires extending the spatial and temporal dimensions of our thinking and practice. Furthermore, it requires protecting the next generation of life. The social contract only protects those within the boundaries of a nation-state and excludes non-citizens, those too young to vote, the disabled, and those who are voiceless, including sentient beings (Faist 2009; Nussbaum 2006).

Accelerated climate change will adversely affect well-being and sustainability (Flannery 2010; Lovelock 2006, 2009; Singer 2002) if we continue to live in ways that consume at current rate. The impact is likely (Rockström et al. 2009) to have been underestimated by the Intergovernmental Panel on Climate Change (IPCC) (2001) and the Stern Review on the Economics of Climate Change (2007) (<http://webarchive.nationalarchives.gov.uk/>, http://www.hmtreasury.gov.uk/independent_reviews/stern_review_economics_climate_change/stern_review_report.cfm).

The problem of how to control the use of scarce resources in a sustainable and democratic way is the focus of this section. The IPCC formula that addresses the implications of polarizing people versus the planet is as follows: E (emissions) = population $\times$ consumption per person $\times$ energy efficiency $\times$ energy emissions (Intergovernmental Panel on Climate Change (IPCC), [http://www.](http://www.bing.com/search?q=intergovernmental+panel+on+climate+change&src=IE-SearchBox&FORM=IE8SRC)

[bing.com/search?q=intergovernmental+panel+on+climate+change&src=IE-SearchBox&FORM=IE8SRC](http://www.bing.com/search?q=intergovernmental+panel+on+climate+change&src=IE-SearchBox&FORM=IE8SRC)).

The IPCC has concluded that the goal of reducing the carbon footprint should be 387 parts per million of carbon, and Rockström et al. (2009) have argued that it should be less, namely, 350 parts per million.

The United Nations Human Development Index (2003) and World Wildlife Fund (2007) show that (with the exception of Cuba) no country in the world has achieved both the quality of life and a sustainable ecological footprint (Wilkinson and Pickett 2009, cites Planet Ark Trust 2004). More equal societies are more sustainable in their attitudes to resource use.

The attitude to what constitutes normal usage of the planet's resources is unsustainable. Democratization to ensure a fairer use of the world's resources needs to ensure that a redesign of living standards occurs – and in the meantime governance controls need to achieve both the contraction of resources (Beck 2010) used by the rich and the greater convergence across living standards for all. In a post consumerist world wealth needs to be re-evaluated, because, to draw on and apply Einstein's well known aphorism: We cannot solve the problems of today with the same ideas of *property and consumption* that created the problem of an *unsustainable* way of life.

Consumption choices have reached a stage where they pose an existential risk (Bostrom 2011). Furthermore, consumption is very unequal, and the gaps between rich and poor become wider and wider. The root cause of consumption is power without responsibility – so whoever comes to power needs to be held to account through mechanisms to develop social, economic, and environmental indicators that secure the well-being stocks for the future. The axiom for systemic ethics is that “we can be free and diverse to the extent that our freedom and diversity does not undermine the rights of others” (McIntyre-Mills 2010). The nation-state has not protected the global commons or ensured social justice for all. This has implications for representation, accountability, and sustainability and the need for a global

covenant to protect the global commons (Held et al. 2005).

Balancing Rights and Responsibilities

Too much freedom can be as bad as too much control. Balancing rights and responsibilities is the challenge for *developed* nations that have large carbon footprints and that seek to access the last of the nonrenewable energy supplies as a means to maintain their international positions and for *developing* nations that need to achieve a decent quality of life to meet the United Nations Millennium Goals (<http://www.globaleducation.edna.edu.au/globaled/go/pid/3740>).

In more equal societies, people consume less and are also less status conscious. Thus, the link “between greater equality and the prevention of global warming involves consumerism” fuelled by advertising. According to their research, greater social and economic equality “gives us the crucial key to reducing the cultural pressure to consume” (Wilkinson and Pickett 2009, p. 221; Hoggett 2010).

“We are part of one space ship, earth” (Buckminster Fuller 1979). We are not in “separate life boats.” The difference between these metaphors is at the heart of the systemic versus the compartmentalized “zero-sum” approach to governance. Systemic ethics requires facing up to the implications of living at the expense of others and future generations, by recognizing the limits which are set by the available resources and the “boomerang effect” (Beck 2002) of carbon emissions, excessive consumption, and greed. Us/them worldviews need to be transformed though the desire to identify with others and the environment. This will lead to enhanced well-being. Xenophobia could be redressed through recognizing that we are global citizens in overlapping regional areas. It is possible to address zero-sum approaches to governance if we avoid the mistaken notion that we gain at the expense of others or at the expense of the environment or the next generation of life.

The environment is a living entity which codetermines our very existence. It is not a

commodity from which to extract endless profit. Ethical decisions ought to be translated into ethical praxis.

The test for whether thinking and practice is ethical is (a) whether it advances knowledge in the area of environmental politics by addressing the tensions across communities’ participation in decision-making (i.e. democracy, human rights) and whether it advances approaches to address both the livability and sustainability of their geographical areas. One of the ways these tensions could be resolved is by applying the United Nations Aarhus Convention 1998 (see <http://aarhusclearinghouse.unece.org/resources.cfm?c=1000069>) on (a) the right for local people to participate in environmental decision making to address food security for their children (b) through invoking Local Agenda 21 1992 policy, and (c) a through an enhanced and extended form of the United Nations sponsored biosphere approach to support educational, scientific and cultural organization. Ideally people living in an area need to be enabled to take part in decision making and to extend their support for their policy concerns within the wider region.

These are some of the policy challenges locally and internationally that need to be addressed, but the **will** to achieve sustainable human rights across nation states requires an understanding that we need to think beyond “us/them” national competitiveness for resources.

Emotions have an impact on personal and public **desire and the political will to make changes**.

Narrow pragmatism is based on thinking about the consequences only for ourselves and not others. We tend to think that social and environmental considerations are “externalities.” Expanded pragmatism (EP) provides a step towards supporting systemic ethics based on extending the capability of humanity to think in terms of the consequences of current social, economic, and environmental choices on resource management for current and future generations of life.

Systemic ethics is the capability to think and practice critically, in order to match appropriate kinds of knowledge to particular areas of concern. Being able to think critically and systemically

needs to be buttressed by post-national constitutions that provide the scaffolding to support deep-ranging environmental changes that shape and are shaped by social, cultural, political, and economic thinking and practice.

Summary

To sum up, our environment shapes the life chances of human beings who in turn shape the environment in ongoing recursive cycles (Bateson 1972). Human beings have the capacity to design their relationships in such a way that they rethink representation, accountability, and sustainability in terms of the consequences for others and the next generation of life. This requires a cultural shift in the current understanding of time, space, as well as rights and responsibilities as global stewards. This has implications for democracy and governance.

Wide-ranging and radical change to the structure of society is required to ensure social and environmental sustainability.

Introduction

Taste and distaste are influential constituents of our relations with food. This essay describes their nature and interconnections and highlights their links with disgust. Reviewing difficulties that arise for the notion of taste (and hence for that of distaste, which has received far less attention), the article turns to literary and philosophical investigations of material life to suggest alternative ways of comprehending taste, distaste, and their bonds with food.

Theories of taste lie at the heart of the notion of the aesthetic in Western philosophy. Traditionally, such views evince an ambivalent stance toward food, one that deploys gustatory taste as a model for aesthetic taste yet also distinguishes these two kinds of taste from one another, decidedly ranking the latter above the former (Bourdieu 1984; Korsmeyer 1999). Carolyn Korsmeyer documents how the historically discredited position of food and gustatory taste in aesthetics reflects a tendentious hierarchy between mind and body, a

correlative privileging of the so-called higher over the supposedly lower senses (which include also touch and smell), and a pervasive neglect of food's cognitive import. She observes that these forces make their appearance even in a range of defenses of the aesthetic status of food and of artworks that take food as their subject matter. In her alternative account, food's context-dependent cognitive and experiential resources invest it with a profuse variety of aesthetic meanings. Besides expressive and representational dimensions, such meanings encompass the corporeally intimate and social aspects of eating and its ability to yield extraordinarily intense memories.

Enlightenment theories of taste and their descendants in philosophy and cultural theory have given rise to a broadly accepted perspective that places taste at the core of the idea of the aesthetic. In laying out standardized, generally applicable criteria designed to validate judgments of taste, philosophers have simultaneously circumscribed a field of human practice and meaning constituting the so-called aesthetic realm, an area of activities harboring distinctive kinds of values, experiences, and norms (see Roelofs 2014, p. 55).

While complexities surrounding taste speak to wide-ranging and profound difficulties under debate in philosophy and cultural theory, they do not give reason to jettison the concept of taste or the aesthetic. Enlightenment constructions of taste exhibit philosophical, ethical, and political problems that reveal shortcomings in the notion of the aesthetic but also point up avenues of response. Taste, distaste, the aesthetic, and food are densely interwoven with many intricate facets of our lives, provoking meanings and questions that literary and other artistic inquiries often are able bring into sharp relief (see Korsmeyer 1999, pp. 8–9, 146–7, 185–6). Particularly intriguing in light of the possibilities and limitations of taste are undertakings by authors such as Franz Kafka and Clarice Lispector to conceptualize forms of change – social, corporeal, imaginary, symbolic – that involve mutations in the areas of eating and food, including developments of the gustatory aesthetic tastes and distastes of their fictional characters (Kafka 1915/2003; Lispector 1964/1988).

These writers implicitly stress the interconnectedness of our sensory desires for eating with other aesthetic registers in which we conduct our relationships with other humans, nonhuman animals, and the material world. They situate disgust alongside an array of sensory attractions and aversions in a field of shifting relationships. Food tastes appear to carry out their aesthetic operations, in part, as devices that steer trajectories of material becoming; they contribute prompts as well as obstacles to processes by which agents attempt to realize alternative ethical and political possibilities within hierarchical social arrangements. Kafka and Lispector thus provide insight into the complex ethical status of food tastes, broaching a field of questions that contemporary scholars also take up in studies of food, taste, and disgust (Korsmeyer 1999, 2011; Ahmed 2004) and the materiality of social change (Braidotti 2002; Bennett 2007).

Taste and Distaste: Philosophical Perspectives

The concept of taste, as we inherit it from eighteenth-century philosophical giants such as David Hume and Immanuel Kant, refers to the human capacity to undergo aesthetically appropriate responses in relation to objects of nature and cultural artifacts, including artworks. The appreciative reactions issuing from the operations of the faculty of taste instantiate a dimension of aesthetic normativity, or, in short, value-ladenness. The value-bearing kind of experience that results from taste's workings is typically called aesthetic experience. Taste, on this widely accepted philosophical view, consists then in a propensity for aesthetic experience. The faculty can be exercised well or poorly. Most philosophers assume it to be educable, that is, liable to improvement through acculturation. Taste prevalently counts as a source of pleasure as well as displeasure: good taste, in influential perspectives along these lines, offers us pleasure in relation to aesthetically worthy objects of appreciation; it engenders displeasure (or distaste) in confrontation with aesthetically unworthy elements. Bad taste gets these matters

wrong. Taste's normative character further reveals itself in its role as a faculty of judgment or evaluative experience: suitably functioning taste is standardly understood to respond with approbation to aesthetic value and with condemnation (or, again, distaste) to aesthetic disvalue. Contemporary philosophers frequently believe our proper taste reactions to apprise us of the aesthetic qualities of the objects of our aesthetic perceptions. They have formulated numerous proposals to this effect, often reworking Kant's view of the disinterested functioning of our common cognitive faculties or Hume's account of the true critic (Kant 1951; Hume 1998).

Kant and Hume are influential precursors of the prominent view that locates the aesthetic domain at a distance from practical considerations. Their alignment of taste with disinterested attention and freedom from prejudice, respectively, lends support to the notion of aesthetic autonomy. At the same time, these philosophers invest taste with significant moral weight. Both recognize an elaborate set of connections between aesthetic and ethical meanings and evaluations. The existence and importance of such bonds between aesthetics and ethics are fairly uncontroversial in current scholarship, even if questions about how these ties are to be conceived are subject of heated debate.

Taste Versus Distaste

Taste, understood as a culturally situated faculty, enjoys greater prominence in aesthetic theory than distaste. Far from the antithesis of taste, in the sense described above, distaste generally implies a tendency to entertain aesthetic responses that include elements of aversion and displeasure. Many young children profess a distaste for Brussels sprouts; such children are inclined to pass over these vegetables, which they experience as repulsive or appalling. Distaste, so conceived, involves a propensity to react with displeasure to objects of aesthetic antipathy; it constitutes a component of taste, defined as a portal guiding us toward aesthetic experience. There is of course a sense in which taste and distaste are opposites.

“Taste” regularly denotes an aesthetic inclination toward sensory enjoyment of substances or objects, as when we say of children who look forward to eating green beans, that they have a taste for these vegetables; they find them tasty. This sort of taste does indeed stand in contrast to the kind of distaste identified earlier. But the broader notion of taste as a proclivity to undergo aesthetic experience includes both taste and distaste in this narrower sense.

The above vegetable examples focus on taste’s axes of pleasure/displeasure and desire/aversion. Yet the same point applies to its specific workings as a capacity for judgments of aesthetic value and disvalue and for a host of value-inflected “qualitative” experiences of aesthetic properties: the faculty of taste comprises not only taste, understood as a tendency to appreciate aesthetic goodness – as when you have a taste for crispy lettuce, judging its fresh leaves to have a sprightly taste and experiencing their textures, flavors, looks, and sounds as frisky to the taste; it subsumes also distaste, comprehended as a propensity to denounce aesthetic deficiency – as when you have a distaste for overcooked brussels sprouts, judging these mealy blobs to have an insipid taste and experiencing them as flat or bland to the taste.

Taste, Distaste, and Disgust

Distaste and disgust are not the same (Jones 2000). Distaste involves a kind of sensory aversion, a form of displeasure, or a type of disapproval that can draw on a great variety of other experiences, including disgust. For example, instances of distaste can involve elements of the grotesque, the uncanny, formlessness, abjection, or the horrific. Furthermore, a distaste that turns us away from celery need not have us recoil in disgust. Disgust displays its own, distinctive contextually based, cognitive and experiential structure, which engages us in an immediate visceral reaction and often manifests aspects of attractiveness and fascination (Ahmed 2004; Korsmeyer 2011), components that distaste does not require (see also Nussbaum (2004, pp. 87–8, 94–6, 121)). The

affect of disgust is typically taken to rely on bodily proximity (even if mediated through a chain of contacts among elements (Ahmed 2004, pp. 87–88) or imaginings (Korsmeyer 2011, pp. 30, 56–7). Korsmeyer ascribes to disgust, aroused as a constituent of aesthetic experiences of food, art, and other elicitors, a unique power to offer an intimate apprehension of death, transience, and bodily dissolution. In short, differences between distaste and disgust abound.

However, Pierre Bourdieu surmises that “tastes are perhaps first and foremost distastes, disgust provoked by horror or visceral intolerance (‘sick-making’) of the tastes of others” (Bourdieu 1984, p. 56). This speculation hints at complex affiliations among taste, distaste, and disgust. Bourdieu suggests here that aesthetic taste counts taste among its objects, being substantially *about* taste(s), and proposes that this disposition functions by way of distaste and disgust. He alerts us to the possibility that the three phenomena enter into one another’s workings, an idea that, we shall see, is also borne out by several literary treatments.

Critiques of Taste

Taste faces pressure from the sides of art, theory and a variety of other social practices. Artists and scholars have recognized ways in which longstanding asymmetries involving race, class, gender, ethnicity, coloniality, and nation permeate aesthetic experiences, standards, and judgments, at the level of philosophical analysis and everyday cultural existence. At issue are systemic phenomena, such as the fact that creations by white European men have generally been considered of greater aesthetic value than ones by African women. In tandem with this line of criticism, thinkers have examined the contributions of aesthetic elements to constructions of social difference and hierarchy (Bourdieu 1984; Shusterman 1993; Korsmeyer 1998; Roelofs 2014). For example, food tastes, such as an appetite for light, or, to the contrary, heavy and fat foods, regularly appear to serve as grounds for distinguishing classes of eaters from one another (Bourdieu 1984, p. 185). The entwinement of aesthetic matters with unjust

forms of social differentiation engenders a host of ethical and political quandaries for philosophy, cultural theory, and social collectives: what place does and should the aesthetic occupy vis-à-vis the various markets surrounding the production, consumption, and exchange of cultural artifacts? More specifically, how might we conceive and reconceive the functioning and the philosophical underpinnings of taste? What role should we accord aesthetic experience and evaluation, understood in their full richness and complexity, as dimensions of our engagements with one another and the world and of food practices in particular? (On these questions, see Korsmeyer 1999; Heldke 2011, 2012a, b; Probyn 2012; Roelofs 2014).

Numerous artists explore intricately interwoven aesthetic and ethical conundrums surrounding eating and food. Franz Kafka and Clarice Lispector, among others, accord sensory desires for and aversions toward edible materials an organizational role within webs of power and discipline (Kafka 1915/2003; Lispector 1964/1988). These authors mark out a significant place for taste and eating rituals, which, in their texts, function both as impediments to processes of change and as sites at which transformations are revealed to disrupt boundaries of gender, class, and race and to upend divisions between human and non-human life forms.

Food, Taste, and the Orchestration of the Ordinary

Our tastes and distastes form an integral part of the organization of everyday existence. In Kafka's novella *The Metamorphosis*, breakfast constitutes a regular feature of family life, one that typifies also the routines of a commercial traveler such as Gregor Samsa, the story's protagonist. Upon his mutation into an insect – or, more precisely, a verminous being of an unspecified sort – Gregor's habitual desires for food undergo a sea change. Sweet milk, formerly his favorite drink, no longer holds any appeal to him. Attentively left for the creature by his sister, the substance currently fills him with aversion. In his present condition,

Gregor's preference turns to half-rotten vegetables, a hardened white sauce, and, most of all, a chunk of cheese he had declared inedible just two days ago, when matters in the home were still run as usual. Shifting social and domestic arrangements precipitated by his transformation prominently materialize in the realm of food. The cook resigns. The father puts an end to his prolonged breakfast ritual, during which he customarily absorbed physical nourishment along with the news. Financial exigency forces him to supply bank clerks with breakfast and, as the predicament of his son-turned-insect persists, to prepare meals for lodgers who take up quarters in the house. Mother, father, and sister eat and drink less and less. Their mealtime discussions dwindle. As life goes on, the sister, in her brother's eyes, grants him whatever edibles happen to be around in the house, apparently having lost all consideration for what he might or might not wish to eat. Kafka imagines the turnabout visited on the family in terms of a changeover in what is eaten, how, and when. He asks us to contemplate a revision of the bonds between food and work, along with an adjustment in what elements are prepared and presented for digestion by whom and for whom.

The uprooting of the family's fate takes place as a development within foodstuffs: items that were previously considered refuse, waste, and leftovers, in the current situation, satisfy Gregor's hunger and offer him gustatory pleasure. Materials gain new functions. To expel his son from the living room he has entered, the father takes recourse to the fruit bowl, fielding a cannonade of apples at the insect, one of which harms its back. Delectable dishes thus not merely become repulsive, while unpalatable remnants turn scrumptious, but food also acquires a different, nonfood-based utility under the altered domestic circumstances.

Reverberations in the social armature encompassing the material paraphernalia of food extend yet further than this: analogous substances engender correspondences between body parts and objects molding the shapes and movements through which we usher food. On the first morning of his new incarnation, locked up in his bedroom, Gregor attempts to unlatch the door by

turning the key with his jaw. The endeavor demands a great physical exertion on his part, one that injures his maw. A brown fluid runs from Gregor's mouth, which flows over the key to drip onto the floor. Yet the bug's effort is successful. Shrinking back from the creature, who has been coming all too close, the mother bumps into the breakfast table set behind her. A large coffee pot tumbles from the table and spills a flood of coffee over the carpet. Bringing together and yet separating the worlds of human and non-human animals, and subverting the distinction between processes transpiring inside and outside the body, the two brown liquids forge an uncanny resonance between the neither fully human nor altogether nonhuman orifices represented by the mouth and the kitchen utensil, between the ambits of bodily experience and material artifacts (key, coffee pot, carpet), and between the purview of intentional animal agency and involuntary human response. The dividing lines partitioning these elements appear to be mobile. At this point, the reader's sense of bodily integrity becomes somewhat destabilized. Kafka renders the shake-up afflicting the Samsa household tangible as an overhaul of body parts, objects, and corporeal acts involved in the handling, consumption, and expulsion of foodstuffs.

Tastes and distastes guide the characters' behaviors in multiple sense modalities throughout the story. Gustatory, olfactory, and tactile attractions and repulsions in the realm of food collaborate with desires and aversions embodied by the other senses to orchestrate an array of material and symbolic relationships among persons, animals, humans, objects, and spaces. Among the propensities structuring these relationships are auditory sensibilities (Gregor's appreciation of his mother's voice, mirrored inversely by individuals' fear of the sounds he utters), visual likings and loathings (the parents' ultimately high regard for the sister's looks, which parallels their disdain for the brown mass that is Gregor), and tactile and proprioceptive conditions (such as Gregor's initially uneasy settling into his body, his continued experience of his own bodily states, and the presumably repugnant quality to human touch of the slimy traces he leaves in his path). Tastes and

distastes comprise dispositions that are instrumental in the steering of our daily comportment at the level of multiple, conspiring sensory registers.

Gregor's aesthetic aversions to food connect his life as a commercial traveler with his existence as a bug. One of the hardships of his itinerant existence used to be the inevitability of bad, irregular meals. His metamorphosis intensifies the trials he undergoes with respect to the necessities of eating and drinking and the conferral and withholding of provisions. The insect's tastes and distastes exert a humanizing effect. They signal capacities he shares with human beings. These sensibilities, which make food matter to him in specific, ethically salient ways, call for moral regard. They are instrumental in upholding his moral standing, in the reader's eyes. His companions' indifference to the pleasures, pains, and meanings sustained by his phenomenal world bespeaks their callousness. Their disgust proves to be decisive to the unfolding of the domestic ordeal. The family finally finds relief from its misery in ridding itself of the bug. Upon his death, the cleaning lady expeditiously removes the corpse, which has evidently been demoted to dirt or trash. Disgust, at once morally problematic and soliciting respect, does not permit us to separate the animal from the human across a rift between, on the one hand, the position of rebel or victim and, on the other, that of boss, patriarch, petty bureaucrat, or collaborator in oppression, because the cleaning lady (who participates in Gregor's expulsion and who we can assume to be human, even if presumably not as unwaveringly human as her employers) is the one and only creature not driven by disgust – Gregor as well as his family members participate in this emotion. The affect does not straightforwardly connote humanity or a deficiency thereof; and neither does the absence of disgust clearly intimate these conditions. Kafka registers taste's, distaste's, and disgust's ties to categories of living beings and objects (class, gender, person, animal, thing, food/nonfood, useful/disposable object) and the tangled fault lines such categories tenuously and tendentially specify among various entities.

Gregor's interest in food declines as the story proceeds. The digestion part of his eating comes to an end: he chews substances only to spit them out again. His own disgust mingles with his submission to the disgust of others. The absorption of materials stymied, the emotion manifests a stubborn cyclicalness. Foregrounding Gregor's double standing as a subject *of* taste and an agent who is subjected *to* others' taste and placing the power of disgust in tension with his aesthetically underwritten status as a being worthy of moral consideration, Kafka discloses the thorny ethical significance sustained by taste and distaste (On forms of vulnerability, aggression, and violence emerging in this affective zone, see Nussbaum (2004) and Highmore (2010)). The novella situates the reader in a position of uncertainty, in which the ethical tenability of her aesthetic investments has been called into doubt.

Moving Through Distaste

Clarice Lispector's novella *The Passion According to G.H.* lends the transformative potentialities of eating an importantly different kind of spin (Lispector 1964/1988). Its narrator, the white Brazilian sculptress, G.H., tells us of the conversion experience she underwent the day before, in the course of which she shed the forms of her culturally shaped identity. Intent on putting in order her former black maid's room, G.H., to her consternation, enters a meticulously cleaned space. Under the influence of its barren purity, the grounds of her social being begin to dissolve. She comes to partake of the continuity of living matter, which encompasses, among other things, a cockroach with which she comes face to face in a wardrobe. The difference between her and the animal, two pieces of the same energetic substance, slips away. She abandons the disgust she feels for the insect (impelled by both its attractiveness and repulsiveness [54]) and eats the white pulp that seeps out of the dying bug's broken back. G.H. forfeits her taste for beauty and her distaste for ugliness to allow for a more delicate "taste of the living" (146). Unconstrained by her customary tastes, such as an appetite for the

potato's seasoning that effaces the more delicate taste of the tuber's earthy substance, she is able to experience an impersonal, nonhuman contact with the materiality of things. In this contact she finds a basis for a different kind of goodness and morality. Discarding the trappings of the human, as well as the promise of an "aesthetic plane of goodness" (152), she learns that a true humanization of the human may ensue if humans give themselves over to unknown aspects of their interdependency with the world. That evening she plans to go eating shrimp and dancing with her friends. The eating mouth exemplifies her impassioned, desiring material connection with the world, as she returns to regular happiness.

Shifting the boundaries of eating constitutes a stage in G.H.'s passing through a sedimented form of social being that casts her into a predictable mold toward a more expansive set of relationships with others and the material world. Her metamorphosis clearly takes place in a woman's body and counters gendered philosophical hierarchies such as the indefatigable mind-body opposition. Underscoring the ethical, political, and ontological significance of sex-specific processes of change, Rosi Braidotti describes it as a process of feminine becoming (Braidotti 2002, pp. 160–171). But eating-through-and-into-otherness often engages us in exoticizing quests (hooks 1992; Heldke 2003). Such projects valorize enticing aspects of racial and class difference as instances of ostensibly more general, open-ended types of alterity. G.H.'s case is no exception to this. Her aesthetic desires and aversions both track and fuel intersecting racial, colonial, class, and sexual parameters, modalities that are coded by and play themselves out in the human-animal relation. In contemplating and taking part in the aesthetics and ethics of transformation, we thus need to explore the ways in which eating and food tastes channel or derail such forces, including the forms in which we attempt to dispel already existing forms.

Kafka and Lispector posit a baseline of everyday life in which taste is complicit. This condition of normalcy unravels in consequence of the aesthetic shifts traversed by their characters. Nonetheless, at the end of each story, an ordinary rule of

things reasserts itself, albeit with a material, symbolic difference. These contravening tendencies bring out unsettling ethical predicaments inherent in a long-standing history of taste's relational operations (Roelofs 2005).

Food, Taste, and Agency

Drawing on Friedrich Nietzsche and Henry David Thoreau, political theorist Jane Bennett argues that eating involves a recorporealization of human and nonhuman bodies in response to one another. Both kinds of bodies contribute formative powers to this process and yield materials that are being acted upon by other forces. Bennett rejects what she labels "a conquest model of consumption," which "disregards the effectivity of not only animal bodies, but also the 'bodies' of vegetables, minerals, and pharmaceutical, bacterial or viral agents" (Bennett 2007, p. 133). For food to nourish an eater, she indicates, both have to be changeable under the other's influence. Eating, in her view, consists then of a series of transformations in which food exercises capacities of agency in conjunction with other participants in complexes of bodies, substances, and forces (Bennett 2007, p. 134). As an example of the agency of edible materials, she cites the apparent effects of dietary fat. Several studies of fatty acids have found that lipids influence subjects' cognitive and social states, affecting attention span as well as rates of depression and aggression. According to Bennett, Nietzsche and Thoreau, likewise, affirm the agentic capacity of food in commentaries on the moral and political efficacy of diet. Both philosophers, along with the more recent slow food movement, she notes, advocate projects of artful (or, as we can call it, aesthetically innovative) eating, with the intention of instigating changes within heterogeneous constellations of elements. To suggest an example, an increase in the consumption of fish rich in omega-3 fatty acids might, by way of a rather unpredictable chain of effects, issue in a greening of your concrete-dominated street corner and a greater incidence of parties, romances, and high achievers in school. Such mixed configurations of

components, labeled assemblages, in Deleuzian terminology, are precisely the flexible material entities that Bennett, more generally, understands as the loci of social and political agency. Although she does not mention taste specifically and her explicit references to aesthetic aspects remain for the most part quite abstract, her discussions of food implicitly outline a prominent place for taste as a force within the collectivities she sees at work in the realization of cultural change.

Bennett highlights how beer, according to Nietzsche, exerts social power in the context of other cultural artifacts, such as newspapers, politics, and Wagnerian operas. She draws attention to the conative potentialities that Nietzsche's figure of Zarathustra attributes to "warrior-" or "conquerer-food," in contrast to what is to be expected from "flatulent vegetables." In Thoreau, she documents a shift from a hunger for raw, wild birds that he encounters in his path to a repugnance he feels for animal corpses. Meat's oozing and dripping put him off; its filthiness troubles him. He then craves the "true flavor[s]" and tastes of freshly picked huckleberries and blueberries, unprocessed by the market (Bennett 2007, pp. 139–142). Bennett next underlines the slow food movement's double focus on environmental, social, and economic stakes and gastronomical aims (these latter goals involve the promotion of the savoring of food, of cultures of preparation, and of communal aspects of these practices).

Although Bennett does not foreground taste, we can readily see how it would be a crucial element of the network of forces and things she theorizes. Food tastes, in the writings she cites, function in collaboration with a wide range of tastes, as they do in Kafka and Lispector. These include desires for sounds, for ostensibly uncultivated contact with nature, and for intimate participation in sociality and cultural forms. Taste, distaste, and disgust, as the above quotes suggest, once more, exhibit a close interconnectedness.

Besides being experiential capacities, our tastes and distastes are institutionalized phenomena. They constitute social forces permeating commodity markets, agribusiness interests, political movements, public health policies, and school lunch programs. They operate at an ontological

level at which subjects and objects evince interdependencies, conferring both malleability and traction on the exchanges among bodies, human and nonhuman. They must be considered fundamental participants in the multifarious capacities for agency exercised by and surrounding food.

Summary

Allied with the moral and the immoral, the concept of taste enjoys a controversial ethical standing. Along with other kinds of aesthetic desire and aversion, tastes and distastes for food fulfill structural roles in the organization of everyday existence. In contemplating complex sorts of bodily transformation, authors investigate how eaters, food practices, and acts of tasting implement shifting categorial alignments among living beings and among living beings and objects. Literary fictions examine how agents, activities, and experiences involved in eating collaborate to enact aspects of cultural change. Novels thereby implicitly or explicitly accord food tastes a vital role in supporting and modifying the social, material relationships we inhabit. These artistic perspectives resonate with recent scholarship in aesthetics (Korsmeyer 1999, 2011; Heldke 2011; Roelofs 2014), affect theory (Ahmed 2004), and materialist approaches to social change (Braidotti 2002; Bennett 2007). At the same time, the philosophical and ethical conundrums engulfing our aesthetic proclivities indicate that important questions about the makeup, the grounding, and the cultural functioning of our tastes and distastes remain open, calling for further inquiry.

Technologies Used for Animal Breeding, Ethical Issues

Introduction

Animal breeding, as part of domestication, has a long history going back more than 10,000 years (FAO 2007). The selection of animals with desired traits and the crossbreeding of different lines have resulted in many different breeds of use to humans. For most of that time, the required knowledge and skills were developed by means of practical experience. However, since the nineteenth century, scientific knowledge has increasingly been utilized in the practice of breeding. Until the second half of the twentieth century, however, most breeding technologies were still based on the natural mating of animals. After World War II, nonnatural reproductive technologies were commercially introduced and served to accelerate the breeding process. Artificial insemination (AI) in cattle, for example, has replaced natural fertilization in many Western countries. Another, more recent technology is the introduction of embryo transfer (ET), which consists of removing embryos from a female donor and transplanting them into recipient animals, where they will develop until birth. More recently, biotechnologies such as marker-assisted selection (MAS) have been developed; these can speed up the breeding process, because embryos can be tested for desired features before transplantation (Mapletoft and Hasler 2005; FAO 2007).

Breeding technologies have resulted in an enormous increase in food production based on animals. For example, Rauw et al. (1998) describe how cow milk production per lactation in Norway, the United States, and the Netherlands has doubled in the second half of the last century, that the slaughter weight of broiler chickens in the United States and the Netherlands has increased by 50% in the last third of that century, and that the daily growth rate of pigs in Norway and the Netherlands increased by more than 13% between 1980 and 1995.

To be clear, this increase in animal production is not just the result of improved breeding technologies but should also be considered as the result of a combination of various technologies and scientific breakthroughs, such as the application of antibiotics, improved feed content, housing conditions, mechanization, and so

on. This could only happen in combination with a change in the livestock production system in a more general sense. For example, Orland (2003) describes how the rise of high-productivity dairy cattle in Germany and Switzerland in the nineteenth and twentieth centuries was made possible by a change in consumer milk demands and the introduction of train transport that made the importing of feed economically feasible. It changed local farming – which was traditionally based on the interrelationship of soil, animals, and fodder on a local scale – into the practice of external inputs and external markets. This has led to what is sometimes referred to as industrialized animals (Harfeld 2010). Critics point to the fact that the benefits have occurred at the cost of the animals. For example, this has resulted in negative immune performance and higher mortality rates among broiler chickens and to leg weakness and diseases in pigs and cows (Rauw et al. 1998). It also threatens animal agro-biodiversity because of the selection focus on a limited number of traits such as milk, meat, and egg production and an adaption to and tolerance for certain housing conditions (FAO 2007).

The technologies described so far are essentially based on technologies that have resulted in breeds that could, in principle, have also been obtained through classical breeding approaches based on natural mating. This is not the case with the most recent technologies such as genetic modification and cloning. Genetic modification or engineering is the artificial modification (alteration, insertion, or deletion) of genes in living organisms. Unlike breeding, this technology is not restricted by the species barrier. Genes from completely different species may be inserted into the genome of an organism, which can then lead to novel features. Cloning refers to reproductive technologies by which a new organism is produced from a somatic cell or tissue. The new organism will have the same genetic makeup as the original organism from which it was cloned.

A well-known and early example of genetic modification in animals is the “Beltsville” pigs created in 1989 in Canada. These pigs were equipped with a human growth hormone gene that caused them to grow faster. However, they

suffered from several serious abnormalities and diseases, and accordingly the experiment was halted (Thompson 1997). Another example is the genetically engineered “Bull Herman” that was born in 1990 in the Netherlands. This animal had received the human gene for the hormone lactoferrin. The idea was that this hormone could be harvested from the milk from its female offspring for medical purposes. This application led to widespread concern among the Dutch public, especially since this was considered as offending the intrinsic value of the animal in order to equip it with a human gene (Schroten 1998).

A more recent example is genetically engineered Atlantic salmon. This fish species is equipped with genes from the Chinook salmon and the ocean pout and is meant for fish farming (<http://www.aquabounty.com>). It grows nearly twice as fast as the original salmon and is much more feed efficient. Accordingly, this application has also met with societal resistance, especially on ecological grounds. Critics are afraid that the engineered fish may irreversibly and negatively affect natural salmon populations if they escape into marine ecosystems (Smith et al. 2010).

Another very recent application of animal biotechnology has been described in a report of the Dutch Committee on Animal Biotechnology (CBD 2011). This committee advises the Dutch government on the ethical issues of animal biotechnology in non-biomedical applications. In the proposed application, male but not female chicken embryos would receive a gene inserted that codes for a fluorescent protein. This would make it possible to identify male embryos in freshly laid eggs noninvasively and then to exclude them from the brooding process. It could prevent the annual killing of hundreds of millions of day-old male chicks that cannot be used in the egg-production poultry industry. This killing practice is currently the object of criticism in political circles in the Netherlands, and several alternatives, including genetic modification, are being investigated (Leenstra et al. 2011).

The cloning of animals as a reproductive strategy has also resulted in great deal of societal concern. Dolly the sheep, born in 1996 in Scotland, was the first mammal to be successfully

cloned, and acknowledgement of this event caused a shock among scientists and citizens, because it had been generally believed that mammal cloning was really not possible. After the acknowledgement of the successful cloning of Dolly, a full-blown debate raged in many countries, since many saw it not only as a threat to animal welfare and animal dignity but also as a first step towards future human cloning. Cloning may in the future contribute to animal industrialization, because it makes it possible to rather rapidly replace one herd with another. Currently, more than 20 mammal species have been cloned. Most applications are still in the research phase, but some have already been applied, especially for the preservation of breeds with specific traits or for sporting purposes, for example, in horse racing (COGEM 2011).

Ethical Issues

Many ethical issues have arisen with respect to modern breeding technologies, because they have an impact on the welfare of animals, on agrobiodiversity, or on the environment. In addition, the rise of modern biotechnology in the form of genetic modification and cloning has specifically brought up fundamental issues with respect to the intrinsic value of animals and the role of animal technology in present-day society.

Animal Ethics

Already in the early 1960s, there were many authors who took into consideration the moral position of animals. The publication of *Animal Machines* in 1964 by Ruth Harrison especially raised a great deal of public concern (Van de Weerd and Sandilands 2008). The book describes how the focus on efficiency was taking place at the expense of animal welfare when it came to castration, tail docking, beak trimming, dehorning, etc. In response, the British government set up the Brambell Committee in order to investigate this issue. The resulting report stated that “farm animals should have the freedom to stand up, lie down, turn around, groom themselves and stretch their limbs.” This viewpoint

was accordingly adopted and codified into “Five Freedoms” by the British Farm Animal Welfare Council (<http://www.fawc.org.uk/freedoms.htm>). Farm animals should be free:

1. From hunger and thirst – by ready access to freshwater and a diet that maintains full health and vigor
2. From discomfort – by providing an appropriate environment including shelter and a comfortable resting area
3. From pain, injury, or disease – by prevention or rapid diagnosis and treatment
4. To express normal behavior – by providing sufficient space, proper facilities, and the company of the animal’s own kind
5. From fear and distress – by ensuring conditions and treatment which avoid mental suffering.

Except for Freedom 4, this approach reflects a subjective welfare approach towards domesticated animals: The (subjective) experience of the animal itself, although sometimes difficult to assess, should be decisive when it comes to what is considered to be a violation of the interest of the animal. In contrast, Freedom 4 refers to a functionalistic view, where welfare is considered in terms of the normal functioning of the animal with respect to health, growth, and physiological and behavioral aspects.

The Five Freedoms express a code of morality, that is, a set of moral rules humans should follow with respect to their behavior towards animals that fall within the aegis of their responsibility. However, ethics is much more than simply expressing the kind of moral rules we should follow; it also attempts to explain *why* we should follow such rules. It explains why animals have moral standing, that is, why they should be considered as members of the moral circle. Three types of answers, representing the various main theories in animal ethics, predominate: utilitarian, animal rights, and biocentric answers.

Utilitarian Considerations

Utilitarianism is a consequentialist form of ethics, which argues that avoiding suffering or enjoying life is considered to be intrinsically valuable for

sentient beings, including human and nonhuman sentient animals. Consequently, animals are within our moral circle if they have sentience, that is, if they possess the morally relevant ability to suffer or to enjoy life. Accordingly, in as much as humans and nonhumans have the ability to suffer or to enjoy life, they have a similar moral standing. “The question is not, Can they reason? nor Can they talk? but Can they suffer?” – this according to the famous and often cited statement by nineteenth-century philosopher Jeremy Bentham (Gruen 2010). Although this approach is based on the individual properties of affected beings (sentience), it stresses a population-based weighing approach.

According to utilitarian calculus, we need to take into account all effects on well-being of all involved sentient beings when we weigh our actions. Breeding, genetic modification, cloning, etc., may lead to animal suffering but have on the other hand positive consequences for humans, because it contributes to efficient animal production and consequently to human prosperity. However, in some cases, it can also contribute to the animal’s well-being, for example, in terms of increased disease resistance or by becoming less vulnerable to housing conditions or farming practices. This latter may however be questioned from a functionalistic welfare standpoint as it may result in animals that do not show normal and natural behavior.

In agriculture, most of the suggested applications of genetic modifications will most likely not lead to any heavy impact on the animal welfare of the thus-created animals (Thompson 1997). Moreover, regulation in many countries does not allow any genetic engineering and cloning that may result in animals suffering. In the chicken case described above, the inserted gene is not expected to have any effect on the animals. However, we should not just look at those animals resulting from engineering and cloning technologies. Producing these animals in itself often implies many experiments and the use of many animals. For example, hundreds of sheep were needed to bring about the cloned sheep Dolly. And, although procedures have much improved since the 1990s, many animals are often still

needed for experiments, which may also fail and may cause animal suffering (COGEM 2011).

From a utilitarian point of view, one may consider cloning and genetic engineering as not so very different from the older reproduction and breeding technologies. This does not mean, however, that genetic modification or cloning is essentially acceptable. Rather it means that, while the technology itself may not be a moral issue, the possible consequences for the welfare of the creatures involved should be a primary consideration.

Animal Rights Considerations

A quite different reasoning is applied when it comes to animal rights approaches that are generally based on deontological considerations, meaning that it is not primarily the consequences of an act that should be considered, as is done in utilitarian approaches, but rather the act itself, which should be in accordance with certain principles. Taking an example from human society, one should respect, on principle, other people as autonomous individuals. Similarly, according to animal rights approaches, animals have moral standing because of what they are: sentient beings having subjective experiences, that is, the ability to experience the quality of life and to enter into and maintain relationships with others (Regan 1983). Such beings have an inherent or intrinsic value, and our behavior towards them should express this. Inherent value is, according to Regan, “a categorical concept. One either has it, or one does not. There are no in between. Moreover, all those who have it, have it equally. It does not come in degrees” (p. 241). Following this line of reasoning, it is thus not suffering as a consequence of sentience but the ability to have sentience itself that counts.

According to this line of thought, cloning and genetic engineering of sentient beings (and actually all modern animal technologies that aim to contribute to the food industry) should be considered as offending the inherent or intrinsic value of animals.

Biocentric Considerations

The reasoning in both the utilitarian and animal rights approaches is limited to animals having a

certain level of sentience. However, moral objections against genetic modification often not only refer to sentience and sentient animals but also to those with other backgrounds and often to more organisms. For example, the Bull Herman case, already mentioned in this entry, led to much public opposition, because many people considered genetic modification of animals as playing God and/or as an unnatural act.

Biocentric reasoning especially played a role in this discussion. According to biocentrism any living organism should be considered as a “teleological center of life,” having an intrinsic good in its own right. The organism’s good consists of fulfilling its capabilities and satisfying its needs in a manner suited to the species. Life is worthwhile in itself, and one should respect it as it is and not in terms of anthropocentric presumptions. According to Taylor (1986) all living entities have, because of this own good, an “inherent worth,” as he calls it.

In the discussions on genetic modification of animals, the biocentric approach is often expressed in terms of the animal’s integrity, that is, “the wholeness and completeness of the animal and the species-specific balance of the creature, as well as the animal’s capacity to maintain itself independently in an environment suitable for the species” (Rutgers and Heeger 1999).

Respect for integrity (in addition to welfare and subjective considerations) was also an important consideration in the case of the genetically modified chickens. The committee concluded that the current practice of killing millions of day-old chicks shortly after hatching should be considered as a major infringement of the integrity of the animals. It acknowledges that although integrity on the genetic level was at stake in the proposed application, the genetic modification would probably not affect the chickens’ autonomy, their phenotypical identity, or their vulnerability to diseases (CBD 2011, p. 13). Consequently, the committee agreed that the application was acceptable in terms of animal ethics considerations (however, see the last section of this entry).

In general, according to biocentric approaches, it is not primarily welfare or having sentience but the integrity or authenticity of the animal’s

constitution that counts when assessing the moral acceptability of breeding and reproductive technologies such as cloning and genetic modification, for example.

Environmental Ethics

Welfare, subjective, and biocentric approaches are the main considerations when it comes to animal ethics. However, animal reproduction and breeding technologies such as artificial insemination, embryo transfer, genetic modification, or cloning may also effect the environment such as ecosystems, species, or animal populations, for example. According to anthropocentric environmental ethics, the environment is an ethically relevant entity if it directly or indirectly serves human interests. Anthropocentrism therefore often has a utilitarian flavor. In contrast, according to ecocentric reasoning, ecosystems and populations have an intrinsic value that should be respected and should not be negatively affected or, if so, only for strong, compelling reasons (Brennan and Lo 2011).

Although underlying justifications may differ, these two approaches may converge in practice. For example, agro-biodiversity may be considered as a human interest, inasmuch as it contributes to genetic resources, food, and other services (FAO 2007). Modern breeding technologies may reduce agro-biodiversity and may even imply the disappearance of breeds. This may be accelerated by means of genetic engineering and cloning, since they often focus on a few species or races. The reduction of animal agro-biodiversity not only affects the interests of farmers who earn a living from keeping rare breeds but may also be considered as a threat to breeding in general, because it may exhaust the genetic variability on which breeding depends (FAO 2007).

However, agro-biodiversity is not valued only because of anthropocentric utilitarian considerations such as these. Indigenous animal breeds have evolved under specific, societal, and biophysical circumstances, and they may also have an inherent or intrinsic value as a particular species or breed, or because they represent local and historical human traditions and cultures (FAO 2007).

Genetic engineering of animals may also effect the environment directly. For example, genetically modified animals may escape into the wild and interbreed with wild congeners. Wild species, populations, and ecosystems may subsequently be negatively affected, which is questionable or even unacceptable from the standpoint of environmental ethical considerations. This is the main concern when it comes to the development of the genetically modified Atlantic salmon described earlier. Another example is the environmental introduction of genetically modified mosquitoes to combat human diseases. These mosquitoes are genetically modified in such a way that they will not have viable offspring. By introducing huge numbers of these mosquitoes into a local population that is causing a disease (e.g., dengue fever), the pest population will collapse. However, this implies the possible irreversible introduction of genetically modified organisms into the environment with possibly unacceptable consequences (COGEM 2011).

On the other hand, a number of animal engineering applications are meant to benefit the environment. For example, in the genome of the “Enviropig,” genes are inserted that result in a more efficient phosphate uptake and consequently a lower phosphate content in pig dung, which will thus lead to a lower environmental load (COGEM 2011). The development and commercial introduction was halted, however, because of public concern about this application and resistance to it (Pollack 2012). Finally, a number of people have suggested that modern reproductive technologies, including cloning, may play a role in nature conservation and the preservation of endangered and rare species in the future, although there are many hurdles yet to be surmounted (Andrabi and Maxwell 2007).

Ethics, Animal Technology, and Society

The environment, species, or populations are known as collective entities: They may have moral value of their own as a collection of individual entities and not simply as the sum of the moral values of the individuals. There is also

another relevant collective entity at stake when we consider the rise of modern reproductive and breeding technologies: human society. Technology affects our world, leads to new issues, and makes a particular world possible and thus a particular culture. For example, the introduction of the contraception pill in the 1960s drastically changed sexual morality in Western countries (Fukuyama 1999). More recently, we see an enormous impact from the rise of the Internet and smartphones on how people communicate and interact, which in turn leads to new technologies. Similarly, assisted reproduction and breeding technologies have stimulated the development of large-scale or bio-industrial farming practices, which in turn have led to new technologies such as the application of pharmaceuticals to control the appearance of diseases related to crowded stables. In general, we may say that there is a coevolutionary relationship between technology and society. This means they affect and steer each other. Technology therefore carries with it certain moral codes and should not be considered as simply a neutral driver of societal change.

The interrelationship between technology and society is nicely illustrated in the case of the modified chicken. The killing of millions of chicks in the egg-production industry, according to the report of the CBD (2011), is a consequence of a rationalization process in poultry farming in the second half of the last century. It has led to instrumentalization and adjustment of animals for purposes of efficiency, in a similar way as was already described by Ruth Harrison in the early 1960s.

This has led to separate chicken lines: efficient meat-producing and efficient egg-laying lines. However, the male chicks of the egg lines can clearly not be used for egg production and appear to not be useful for commercial meat production. They are therefore killed immediately after hatching. The committee acknowledges that the killing of these animals directly after birth does not respect these animals as living beings from a biocentric point of view. It is a problem that now seems to be solved by a new technology: genetic modification.

Although the committee considered the genetic modification in the application as morally

less problematic compared to the killing of so many day-old chicks, it has questioned the application from an ethics of technology perspective as perhaps an irreversible continuation and intensification of the instrumentalization and rationalization tendencies in poultry farming. Accordingly, the committee has put forward the question of whether this is what we want as a society or whether we should instead look for quite different trajectories of technological development. The committee also concluded that this last question should be answered in a societal debate and has suggested this to the Dutch government. The example of the chicken case demonstrates that ethical questions of modern animal breeding technologies go beyond the level of animal ethics and environmental ethics. In general, ethical issues related to modern reproductive technologies question our relationship to animals and to our environment and, not least, ask us what kind of society we are really aiming for.

Summary

In this entry we have discussed the rise of modern reproductive technologies in animal breeding that have contributed to an industrialized farming system and consequently to animal welfare problems. Starting with the Five Freedoms concept, we outlined three ethical theories as being those which underlie justifications for attributing moral status and thus respect to animals. Utilitarian considerations focus on the welfare of animals and specifically argue for minimizing or avoiding animal suffering. Animal rights approaches argue that sentient animals should be respected because they have as subjects, experiencing the quality of life, an inherent value, while biocentric approaches stress the moral value of life as an underlying motive for respecting the animal's integrity.

However, animal ethics considerations are not alone in playing a role in this. Animal breeding may affect ecosystems, species, and animal populations. Modern reproduction technologies, for example, may decrease agro-biodiversity that may be questioned from both an anthropocentric and an ecocentric environmental-ethics standpoint.

Moreover reproductive technologies such as genetic modification may affect the ecosystem more directly.

Finally, it is argued that technology and society interact and that technologies carry with them implicit moral codes. Modern reproductive animal technologies put questions on the table that exceed the level of animal or environmental ethics and ask us to consider what kind of society we really want.

Telos and Farm Animal Welfare

Bernard E. Rollin

Department of Philosophy, Colorado State University, Fort Collins, CO, USA

Synonyms

Farm animal welfare and animal physical and psychological nature

There are many reasons why there is relatively scant history of theorizing regarding human moral obligations to animals. First, ethics was largely seen as a highly local phenomenon, governing interactions among limited members of select groups of human beings – witness differing biblical ethical standards for the treatment of Israelites, foreigners, women, slaves, and other subgroups of humans. Second, as St. Thomas Aquinas teaches, animals were not perceived as enjoying genuine moral status. At best, it was obligatory not to treat them cruelly, as they sufficiently resembled humans so that gratuitous abusive treatment of them was likely to eventuate in cruelty towards full objects of moral concern, i.e., human persons. Most importantly, the overwhelmingly dominant use of animals in society was agricultural, being used for the production of food, fiber, locomotion, and power. As I explain below, this obviated much of the need for theorizing about human obligations to animals.

The key to produce success in animal agriculture was *good husbandry*, wherein the farmer placed the animals in optimal conditions dictated by their needs and natures and augmented their ability to survive and thrive by provision of food during famine, water during drought, protection from predation, medical attention, help in birthing, and so on. So powerful is the hold of the concept of husbandry on the human psyche that when the psalmist wishes to create a metaphor for God’s ideal relationship to humans, he uses the Shepherd in the 23rd Psalm. Good husbandry was sanctioned by the most powerful of human

Teetotalism

► Alcohol Abstinence and Sobriety

motivations – self-interest. Failure to provide for the needs of one's animals resulted in diminished productivity – loss of weight, sub-optimal reproduction, and susceptibility to disease. For this reason, only an extremely minimalistic ethic for animal treatment was required – forbidding deliberate, sadistic, purposeless infliction of pain and suffering on animals, and the failure to provide basic sustenance such as food and water – to cover those deviant humans for whom sadistic gratification was more important than productivity.

A philosophical need for a rationally articulated, robust, animal ethics probably arose with the advent in Europe of Cartesian philosophy which denied consciousness, as well as the ability to feel pain or to suffer, to animals. In response, philosophers in the British empiricist tradition felt compelled to provide a basis for moral concern. These thinkers generally worked in the utilitarian tradition and included Bentham, Mill, Sidgwick, Salt, and Singer, as well as and related philosophers such as Hume. Being empiricists, the desire on the part of all organisms to seek pleasure and avoid pain seemed to them to be an observable and obvious basis for ethics that lent itself well to quantification. This focus enabled British moral thought to escape from continental European, rationalistic skepticism, as articulated by Descartes, Spinoza, and Kant, about more complex animal thought that excluded animals from the realm of direct moral concern. Animal ethics could thus be grounded in the common sense awareness that animals experienced pleasure and pain even as humans did; that pleasure and pain *matter* to animals.

Practical, societal ethical concern with animal treatment only began in the mid-twentieth century, as society began to recognize the major limitations of the animal cruelty laws and the ethic of anti-cruelty conceptually underlying them. It is almost certain that less than 1% of the suffering that animals experience at human hands is the result of deliberate cruelty. This societal thrust to supplant the cruelty laws continues to grow, as evidenced in 2004, when no fewer than 2100 pieces of legislation pertaining to animal welfare were proposed in federal, state, and municipal

legislatures across the 50 United States (Flemming, 2005, personal communication).

When I and others began work on improving the moral status of animals in society during the 1970s, the greatest problem we faced was deriving a robust animal ethic that would overcome the limitations inherent in the ethic of anti-cruelty. Equally vexatious was the question of creating an animal ethic that ordinary people would find plausible. While the utilitarian emphasis on maximizing pleasure and minimizing pain had much to recommend it as a basis for animal ethics, it also suffered some severe drawbacks. In particular, I recognized that not every sort of harm humans inflict upon animals counts as pain in any ordinary sense of the word, unless the notion of pain is stretched so broadly as to cover all sorts of misery not usually classified under the rubric of pain. Such states as loneliness, boredom, fear, inadequate stimulation, inability to exercise, separation from offspring or parents, impoverished diet, inability to forage, hunt, or otherwise secure one's own food, and myriad others certainly harm animals, yet do not lend themselves to being arrayed along a single axis of pleasure and pain.

In dealing with this problem, Rollin recalled Plato's dicta that ethics proceeds from preexisting ethics and that in dealing with ethics and adults, one cannot *teach*, one can only *remind*. If society wished to expand the purview of ethics over the treatment of animals, it needed to look towards established ethical concepts with which it was already familiar. People would look to the ethical concepts applied to humans and carry them forward, *mutatis mutandis*, to the treatment of animals.

Recall that, before the mid-twentieth century, the key to agricultural success was good husbandry, which meant taking great pains to put one's animals into the best possible environment one could find to meet their physical and psychological needs and natures (which, following Aristotle, can be called *telos*) and then augmenting their ability to survive and thrive. Thus, traditional agriculture was roughly a fair contract between humans and animals, with both sides being better off in virtue of the relationship. Husbandry agriculture was about placing square pegs into square

holes and round pegs into round holes and creating as little friction as possible in doing so.

The rise of confinement agriculture in the twentieth century, based in applying industrial methods to animal production, broke this “ancient contract.” With technological “sanders” – hormones, vaccines, antibiotics, air handling systems, and mechanization – one could force square pegs into round holes and place animals into environments where they suffered in ways irrelevant to productivity. If a nineteenth-century agriculturalist had tried to put 100,000 egg-laying hens in cages in a building, they all would have died of disease in a month; today, such systems dominate.

At the same historical moment, animals began to be used on a large scale in research and testing, again causing new and unprecedented degrees of suffering.

The amount of suffering arising from these sources far outweighed what is produced by deliberate cruelty. Further, the anti-cruelty laws do not cover these new uses and cannot be twisted to fit practices such as steel-jawed trapping, sow stalls, or toxicology testing, since these exemplify “ministering to human necessity,” which is the standard legal test for cruelty. Since trapping is hardly a “human necessity,” this case graphically illustrates how cavalier the cruelty laws were with respect to animal welfare. Thus, a demand was called forth for a new ethic.

In Western societies, human ethics balances utilitarian considerations – the greatest good for the greatest number – against concern for individuals by building “protective fences” around essential features of human nature; these fences are called *rights*. Rights are a moral/legal notion designed to save features constitutive of individuals’ human nature – e.g., the desire for free speech – from being sacrificed for the general welfare. The logic of this notion is being exported to animals – society wishes to assure that their most important interests, flowing from their *telos*, are not sacrificed and that farm animals live decent lives and laboratory animals have pain controlled.

Direct rights for animals are of course legally impossible, given the legal status of animals as property, the changing of which would require a

constitutional amendment. (Many legal scholars are working to elevate the legal status of animals (Wise 2000).) But the same functional goal can be accomplished by restricting how animal property can be used. Thus, the US federal laboratory animal laws require pain and distress control, forbid repeated invasive uses, require exercise for dogs, etc., unless exceptions to these are approved by the appropriate review committee as being required for scientific or animal welfare reasons. And some European laws have forbidden sow stalls. This mechanism is the root of what I have called “animal rights as a mainstream phenomenon.” This also explains the proliferation of laws pertaining to animals as an effort to ensure their welfare in the face of historically unprecedented uses.

In place of pleasure and pain, society is looking towards the ancient Aristotelian notion of *telos* as the locus of moral concern for animals. An adequate morality towards animals must recognize the full range of possible “matterings” unique to different sorts of animal *telos*, or animal nature, the root notion of Aristotle’s functional, teleological biology. Whereas modern biology focuses on reductionist, molecular, and mechanistic explanations, while Aristotle’s biology emphasizes the unique set of traits and powers that make the animal what it is – the “pigness” of the pig, the “dogness” of the dog.

Aristotle recognized that different animals evidenced different ways of fulfilling the fundamental nature of living things, i.e., nutrition, locomotion, sensation, cognition, and reproduction. Biology studies these functions in different sorts of animals, and it is these functions that constitute an animal’s nature. Secondary school biology is still studied in this Aristotelian way. There is nothing mystical about *telos*; it is simply what common sense recognizes in such sayings as “fish gotta swim, birds gotta fly.” The only departure that must be made from Aristotle today is to see *telois* not as fixed and immutable but as snapshots of a dynamic process of evolution, genetically encoded and environmentally expressed.

Thus, an adequate morality towards animals should address not only pleasure and pain but also the full range of possible “matterings”

following from animals' natures. When one evaluates, for example, gestation crates for sows, they must be compared to what a sow does in nature when she actualizes her *telos*, covering a mile a day rooting and foraging, nest building, building her nest on a hillside so that urine and fecal material will run off, trading off piglet care with other sows, all of which behaviors are impossible to perform alone in a crate. In fact, given the *telos* template, it is evident that fundamental interests of animals determined by their natures are regularly violated in modern agriculture. Their freedom of movement is truncated; they are stopped from eating what they are naturally built to consume by not letting them graze, hunt, or forage; their ability to cope with weather change is aborted, as is their ability to exercise. Denying these natural activities harms the animals in many ways, impeding their exercise of powers they possess to survive.

A nonobvious example of violating animal nature or *telos* may be found in a story recounted by Hal Markowitz. He relates that the Portland, Oregon zoo built a showpiece exhibit for servals, even importing sand and plants from the Kalahari (Markowitz and Line 1990). The exhibit was a dud; the servals lay around in obvious depression, refusing to eat. When Markowitz visited their native habitat, he found that the bulk of these animals' time was spent predating low-flying birds, their main source of food. He told the zoo that, instead of feeding horsemeat in chunks, the keepers should grind the rations into meatballs, which were then to be shot randomly across the exhibit enclosure by a compressed air cannon. The animals' behavior changed overnight; they became excited and active, clearly exercising the predating aspect of their *telos*. Despite the power of the food drive, it was trumped here by failing to accommodate *how* they had evolved to eat. Similar strategies provide for *telos* accommodation for many animals in captivity.

An example from coyote behavior strikingly illustrates how *telos* needs can trump even major physical pain. It has been recounted for years that coyotes, caught in a leg-hold trap, will chew their legs off, enduring terrible pain, rather than submit to immobility. (This is also true for other animals,

such as raccoons.) This is understandable given the coyote's *telos* as a free-ranging predator (or, on occasion, prey). It is not plausible to suggest that the animal chews its leg off to avoid death, since it is not possible that a nonlinguistic being *has* a concept of death, though it clearly understands the inability to escape. Clearly the animal is not chewing the leg in order to escape the pain, as any attempt to chew the leg off will greatly *increase* the pain.

Other animals, wild and domestic, will endure pain and injury to escape close confinement. Though confinement agriculturalists in the United States claim that all the needs of confined sows – food, water, protection from the elements, and protection from predators – are met in confinement, these animals escape when they can, with no reports of any ever trying to return. Chickens will trade ad libitum feeding in confinement for sporadic access to food outdoors. Chickens will also work for food in confinement when given a choice of doing so (Duncan and Hughes 1972). Monkeys and other animals will self-mutilate in deprived, impoverished environments, the pain presumably providing some stimulation, as a counter to boredom (Berkson 1967; Ridely and Baker 1982; Chamove et al. 1984).

Kilgour (1978) cites evidence showing that cattle being exposed to a new herd show a physiological response for 30 days. In animals, the initial exposure to the experimental setting (i.e., major novelty) evoked the largest elevations in plasma cortisol (Mason et al. 1957; Hennessy and Levine 1979). This is not surprising, since cattle are herd animals who come to know their conspecifics as individuals and hence do not know how new animals will behave. Novelty of any sort evokes stress in most if not all animal *teloi*. Even in human experiments, the introduction to the experimental situation for the first time was often more effective in increasing steroid level than anything else the experimenter could devise, including electric shock (Michalski 1998).

Researchers know that animals can be trained by reward to accept some physically painful experimental procedures. In one instance, a

researcher was drawing blood from dogs daily for a vaccine study. She would enter the facility, play with each dog, draw the blood, and give the dog a treat after the draw. On one occasion, one of the dogs set up such a howl as she was leaving that she raced back to see if his paw was caught in the cage door. It turned out she had forgotten to draw blood from that dog, and he had missed his play and his treat, which bothered him more than the blood draw (Kesel, 1983, personal communication). Separation of a newborn calf, routine in modern dairies, can cause mooing on the part of the mother cow bespeaking distress for over a week, even longer if the cow can see the calf (Flower and Weary 2001). This is no surprise, as calves in more natural situations will suckle and remain with the mother for up to 9 months or more.

All of these examples illustrate four major points:

1. Pain, as a physical phenomenon, does not begin to capture all the ways in which what we do to animals matters to them.
2. Other things done to the animals can be worse for them than physical pain. Unfortunately, we have no words for many of the myriad ways we can harm or cause animals to suffer, for example, not allowing the pig to forage, separating a newborn animal baby from its mother at birth, and stopping a chicken from nest building. (For others, of course, we do have words, e.g., creating boredom, social deprivation, and fear.)
3. In general, interfering with or impeding actualization of *telos* creates a negative experiential state for an animal.
4. Appeal to the concept of *telos* provides a far more comprehensive basis for animal ethics than does anything else, including the concepts of pleasure and pain. In addition, the notion of an animal's nature and its moral importance are both plausible and evident to common sense.

A moment's reflection will reveal to any reader the extent to which the vocabulary for dealing with ways of harming animals is impoverished. Virtually none of the ways enumerated above

in animals can be harmed even have names or precise descriptions. Yet, the ways in which confinement agriculture infringes upon and aborts needs and desires built into an animal's nature are legion. Even more importantly, now that husbandry agriculture that respects animal *telos* is virtually universally overridden for the sake of profit, efficiency, and productivity and society condemns the resulting suffering, reference to *telos* provides far greater precision regarding what needs to be restored than does talking about pain. All high confinement systems deployed in modern industrialized agriculture are aptly described in relationship to animal *telos*. Whether one is talking about sow confinement, unnatural diets, tail docking in dairy cattle, restrictions on movement, truncation of play, isolation of veal calves, and the animal's never seeing a blade of grass or sunshine, *telos* provides a measure of the inadequacy of these systems.

It is simply mistaken to refer to such infringements as causing pain. A very simple argument demonstrates this point conclusively. Suppose one could medicate animals in a way that totally abolished any experience of pain. By hypothesis then, the animals would be experiencing no pain and thus no harm and would not be wronged according to utilitarian ethics. Yet, it would be a deviant person indeed who would fail to accept that the animals are being consistently mistreated and wronged by severe limitations on the exercise of their natural abilities.

In the case of all domestic animals, one can further mount the argument that humans are responsible not only for shielding them from harm, but also for assuring them a context in which they can flourish. Acting morally towards horses requires providing them with food, water, shelter, and shade, so as to avoid negative influences on the quality of their lives. But, there is also a moral requirement to provide positive value in their lives, i.e., by helping them be happy. Those who have kept horses know that there are resources that can be provided to these animals that result in positive experiences, for example, when they are given access to a pasture where they can eat, play, and run in relative freedom. Clearly, the equine behavior displayed under such

conditions evidences that these animals are experiencing happiness: galloping out of a pen when they are released for the first time in months, kicking up their heels, and giving the uniquely equine “fart of joy.” In other words, not only does *telos* allow us to home in precisely on all of the harms we inflict on animals in the course of using them, it also provides caretakers with guideposts for assessing the extent to which “negative mattering” can be replaced with positive mattering.

There will of course still be some theorists who believe that the notion of *telos* is unreservedly and unacceptably metaphysical. And, indeed, it *is* metaphysical, in the sense that metaphysical concepts are those categoreal notions we utilize as basic concepts when talking about reality. A concept like *telos*, like other commonsensical concepts such as cause and effect, thing, emotion, and indeed all ethical concepts, do not profess or claim to capture absolute, ultimate reality. Rather, they capture the reality of ordinary experience, daily life, and common sense. And such is the realm of common decency and of the ethics that attempts to capture and to codify it. Even if one is ultimately a scientific materialist and realist, in one’s ethical moments common sense is regnant, and concepts like an animal’s nature occupy center stage.

One can thus argue that the utilitarian concepts of pain and pleasure, as important as they undoubtedly are, are nonetheless inadequate to serve as a comprehensive basis for animal ethics, particularly when ethical questions arise with regard to modern, intensive, industrialized, confinement agriculture. The multiplicity of insults and deprivations inflicted upon animals in such systems are most naturally and plausibly captured by invoking the notion of animal nature or *telos*. The needs and interests that make up what the animal’s nature is inform caretakers when they are harming that animal or behaving in a manner conducive to its happiness in a simple, nonsensical, and straightforward manner. As society begins to address animal ethics in ever finer-grained detail, it is likely that the concept of *telos* will assume ever-increasing importance in the discussion.

Summary

Historically, the overwhelming use of animals in society was agriculture. Since animal production depended on good husbandry, no ethic for animal treatment was needed short of prohibiting deliberate cruelty. Philosophical need for animal ethics arose following Descartes’s denial of animal consciousness and plausibly was answered by appeal to pleasure and pain. It was only when society began to worry about animal treatment in a multiplicity of areas that it became necessary to go beyond pleasure and pain to extend moral concern to all aspects of animal life. Rollin revived the Aristotelian concept of *telos* or nature to accomplish this. Just as human nature, and the rights flowing therefrom, govern our moral obligation to humans, one could plausibly extend this reasoning to animals and base our obligations to them on respect for their biological and psychological needs and natures. Such a move goes well beyond pleasure and pain to meet such natural animal requirements as moving, grazing, foraging, nest building etc., i.e., all the ways animals meet their needs for nutrition, locomotion, sensation, cognition, and reproduction. Thus, animal ethics must be based in respect for *telos*, which is a much more comprehensive basis for ethics than pleasure and pain, and allows us to recognize both positive and negative mattering.

Introduction

The fact that farmers in the poorest countries have very little benefited from the recent price spikes in agricultural commodities is one of the greatest paradoxes of the last few years. Furthermore, in these same countries, city dwellers have suffered just as much from price increases without being better fed by local production. This is why, according to the FAO, the small decrease in the number of malnourished people suddenly stopped in 2007–2008. The reasons explaining this paradox are well established: Third World farmers only have access to local markets. Roads are poor, means of communication are limited, and storage capacities which would reduce the need to sell produce immediately after harvesting are often unavailable. There are no credits at affordable interest rates and very few mutual organizations to facilitate mutual assistance and insurance.

In fact, this paradox asks us about the ethical dimension of international trade. It is urgent to improve international trade relations taking into account the social welfare, economic, and environmental performance of smaller producers and consumers. Ethical trade aims to bring social and environmental improvements in the existing international trade unlike fair trade which is parallel trade. Thus, an international strategy more aware of the ethical issues should encourage us to develop a more appropriate legal framework for

international trade of agricultural products so that trade promotes economic development in poor countries and ensure food security in the world. Such reflection will help us to ensure that ethical issues are not neglected in the international negotiations.

The rising cost of agricultural commodities will benefit the very poor only if agricultural investment is increased and if, perhaps most importantly, the trade capacities of small producers and states are strengthened. This is in fact related to the crucial issue of the link between trade and development: how can trade in agricultural raw materials be better organized and regulated in order for it to foster food security as well as economic development in poor countries? This is an especially important matter as, according to the World Bank, it is in low-income countries that agriculture contributes the most to poverty reduction and general economic development (World Bank 2008).

Commodity markets, sources of income for farmers in developing countries, are in need of ambitious policies and must be a particularly important focus point for the international community. Indeed, 2.5 billion people are engaged in small-scale agriculture in developing countries, and about 1 billion draw part of their income from commodity exports. Ninety-five of the 141 developing countries depend by more than 50% on commodity exports for their export income. In particular, the economies of the least developed countries (LDCs) are based on the exportation of tropical products which account for around 70% of their total merchandise exports (UNCTAD 2011b).

The international economic order has never managed to address satisfactorily the issue of commodity trade. However, in view of the challenges faced by agriculture, the problems tied to commodities must urgently be placed on the top of the international priority list. The goal to achieve is to assure trade in agricultural commodities, thereby ensuring global food security, providing leverage for the economic development of poorer countries, and ensuring also an important source of raw materials supplying the agro-industrial sector of developed countries.

It is thus important to ensure the consistency of trade policy goals with the aims of development as well as with food security. This necessarily requires a new international consensus on development and a reinforcement of development programs in the area of basic agricultural commodities. It also entails taking into account non-trade-related aspects linked to agriculture in order to respect sustainable development objectives.

Legal recognition of a secure and continuous access to agricultural raw materials for importing countries in exchange for a better organization of the primary commodity markets would be desirable. In the absence of an agreement under the WTO Doha Development Agenda framework, reaching a less comprehensive multilateral agreement on basic commodities, based on the model of a partnership and cooperation agreement placed under the auspices of the WTO and UNCTAD, would strengthen international cooperation on the management and trade of basic commodities.

A New International Consensus on Agricultural Commodities

The failure of the Washington Consensus and of structural adjustment programs entails a need for new thinking on development. The current economic crisis has indeed put into question some of the basic paradigms of the economic model which has prevailed in the last couple of decades, as can be seen from certain evolution at the World Bank.

Agriculture has critical capacities in terms of poverty reduction. Agricultural growth has a specific impact on poverty reduction in every category of country. It is estimated that GDP growth attributable to agriculture contributes at least twice as much in reducing poverty as growth in GDP related to the nonagricultural sector. For China, aggregate growth originating in agriculture is estimated to have been 3.5 times more effective in reducing poverty than growth outside agriculture and for Latin America 2.7 times more (World Bank 2008). Agriculture is thus a crucial development tool for the achievement of the Millennium Development Goal of halving by 2015 the number of people living in extreme poverty and

suffering from hunger. This is the core message of the World Bank's 2008 *World Development Report*. Moreover, according to the World Bank, one of the key factors in agricultural growth is the development of agricultural trade. Trade is critical for economic life: without exchange, progress and economic development are impossible. As a matter of fact, trade in basic commodities contributes to three fundamental objectives: global food security, economic development of developing countries, as well as supplying with resource-poor countries.

However, if promoting trade of agricultural products is important, it is also essential to strengthen both production and trade-related capacities of small producers and poor countries which will enable them to sell their products on international markets. Indeed, market access commitments (e.g., reduction of tariff barriers) are rendered useless if poor countries are faced with capacity constraints which restrain their ability to take advantage of these commitments. The Aid for Trade Initiative is consequently indispensable in order to help the countries concerned to integrate themselves in the world market and to exploit their trade and growth potential. The Aid for Trade Initiative was officially instituted following the Hong Kong 6th Ministerial Conference in December 2005. It has been presented as a promising development tool, aiming at furthering trade integration of developing countries. Aid for Trade is about helping developing countries, in particular the least developed, to build the trade capacity and infrastructure they need to benefit from trade opening. For example, investing in the infrastructure – roads, ports, telecommunications, and energy networks – is needed to link products to global markets or strengthening economic to increase competitiveness in export markets. Such efforts also play a major part in achieving the Millennium Development Goals concerning food security and economic development.

Is the Resource Curse Inevitable?

Contrary to popular belief, primary commodities' trade does not necessarily lead to underdevelopment (Bairoch 1993). Trade in mineral raw materials and agricultural basic commodities has often

been linked to a *resource curse* causing impoverishing growth for certain commodity-exporting countries. Though the resource curse is certainly a reality, it is far from being inescapable (Havro and Santiso 2008) as shown by the cases of Norway, Chile, or Malawi. These countries offer valuable lessons to developing countries in terms of sensible management of mineral and agricultural resources. The key to such success stories is due above all to the quality of institutions and reforms which have been instigated over time. Clearly, these countries have been able to devise efficient political and economic governance in order to successfully manage these resources.

If basic commodity exports do not necessarily lead to underdevelopment, nevertheless, the best way to encourage further development remains industrialization as well as product and export diversification. Markets function most effectively when the institutional environment in which they operate is stable and efficient. This entails virtuous political and economic governance which is unfortunately still lacking in many poor countries.

Aid for Trade in Support of Development and Food Security

All studies agree on the need for an increase in agricultural production in order to achieve global food security. However, although increased production is important, it is also essential to ensure the conservation of agricultural products and their proper commercialization. According to the FAO, 630 million tons of agricultural products (or 1/6 of the world's production) are lost in developing countries due to poor storage facilities and a lack of infrastructure enabling proper processing of these products (FAO 2011).

Opening markets and trade preferences by themselves are not sufficient to generate development and ensure food security. Though international trade does potentially have an important role in the fight against food insecurity and poverty, there are some necessary prerequisites in order to be able to seize the opportunities offered by trade. The major constraints in poor countries are low trade capacities and high costs of production. Developing the supply capacity of

agriculture as well as infrastructure (transport, energy, telecommunication) and creating a judicial and economic environment favorable to production thus seem crucial. Moreover, even when they do exist, trade preferences granted by developed and emerging countries to products originating from developing countries are not sufficient as the latter must also meet stringent international norms and standards. Help in achieving compliance with international standards and in improving the quality of products is fundamental.

Aid for Trade – which covers about one third of all public development aid (Lamy 2011) – aims at putting trade at the service of development. It helps countries take advantage of the opportunities offered by the multilateral trading system to generate economic growth and fight against poverty. Providing market access opportunities is a necessary condition, though not always sufficient, to ensure that countries benefit from trade. Other actions are also necessary to help developing countries, and especially the least developed ones, to upgrade their trade-related infrastructure and to overcome the limitations of their production and trade capacities in the agricultural sector. It is therefore necessary to improve the trade capacity of least developed countries to ensure food security of the world and increase the livelihoods for small farmers.

Market Access: A Necessary Albeit Insufficient Condition

During the past 50 years, access to developed countries' markets has been facilitated by a reduction of tariffs and quantitative restrictions, although the practices of levying higher tariffs on finished goods than on raw materials (tariff escalation) and of charging unusually high tariffs on goods thought to be sensitive (tariff peaks) remain very worrying. Tariff escalation may have the effect of protecting processing industries in high-income countries while making it more difficult for developing countries to enter value-added markets. Clearly, market access alone is not a sufficient condition to ensure development gains flowing downstream to commodity producers, traders, and processors in developing countries.

Free trade agreements – whether bilateral or regional – are meant to promote and expand trade. But no matter how noble they may be, they will have very little impact if their potential beneficiaries are not able to produce goods of the quality demanded in the developed countries' markets. For example, duty- and quota-free access for products from the African, Caribbean, and Pacific countries (ACP) to the European Union, under the Economic Partnership Agreements, means little if these countries cannot meet the applicable standards.

One of the major impediments to free market access and trade has been the proliferation of safety and quality standards, not to mention divergent laws and technical regulations. In recent years, legitimate concerns have also increased over the safety and quality of food entering the world market due to health hazards associated with avian influenza, bovine spongiform encephalopathy (BSE, or “mad cow disease”), dioxin in eggs and pork, melamine in dairy products (infant milk), and swine flu. Mycotoxins (toxic elements produced by fungal agents) have also been found in agricultural products, salmonella in peanut products, and pesticide residues in plants.

In response to this situation and in order to safeguard the health of humans, animals, and plants, developed countries, in particular, have adopted a great number of food safety and quality standards as well as legal provisions and technical regulations. Most commodity-dependent developing countries are ill equipped technically to comply with these regulations and standards, whether public or private, and do not have the financial resources to offset the excessive costs of compliance.

Reinforcing Development Programs in the Agricultural Commodities' Sector

Without adequate processing and packaging immediately after the harvest, agricultural losses can represent 60% of the production and that even before reaching the first point of sale. The lack of packages for perishable products meeting international standards also results in huge losses and dramatically reduces profit margins for both

producers and exporters. Africa (apart from South Africa and the Maghreb region) could increase its agrifood exports by 30% simply by improving the quality of its packaging. In Western Africa, on around a 100 billion dollars of exports each year, there is a potential income loss of approximately 30 billion dollars (International Trade Centre 2010).

Compliance with sanitary and phytosanitary standards (SPS) and infrastructure are crucial trade issues for poor countries. These SPS standards significantly reduce the agricultural exports from the South to the North but do not affect North-North trade, confirming the fact that SPS standards have a real impact on trade due to the incapacity of developing countries to meet these norms (Otsuki et al. 2001; Chan et al. 2006). Compliance with international standards can thus be regarded as a major obstacle to the full participation of developing countries in the multilateral trade system.

It therefore seems clear that programs to help developing countries comply with international standards and effectively develop adequate infrastructure would dramatically boost their trade performances. As a matter of fact, a great number of donor agencies as well as intergovernmental bodies and NGOs have started to provide technical and financial assistance to developing countries to enable them to comply to these standards or to obtain certification from well-respected bodies. For example, the Codex Alimentarius (FAO/WHO) finances the participation of developing countries in standardization meetings, and the WTO's Standards and Trade Development Facility (STDF) is funding projects that support developing countries in building their capacity to implement sanitary and phytosanitary standards as a means to improve their ability to gain market access.

However, in 2010, the UNCTAD noted that “Commodity-related policies have often been neglected when it comes to designing national development strategies, which has resulted in missed opportunities for the commodity sector. Although the objectives of the Enhanced Integrated Framework and the Aid for Trade initiative are to assist countries in integrating trade into their

development strategies, commodities are seldom explicitly singled out” (UNCTAD 2010).

The producer’s ability to provide a product that meets the buyer’s requirements in terms of certification clearly depends, on the one hand, on the producer’s knowledge of these requirements and, on the other hand, on having the resources to satisfy such exigencies.

Fuller integration of commodities in the objectives of development strategies based on the Aid for Trade Initiative should thus be a priority on the international policy agenda. The work of the WTO’s Enhanced Integrated Framework (EIF) and of Standards and Trade Development Facility (STDF) should therefore be sustained and reinforced. (The STDF is a global partnership that supports developing countries in building their capacity to implement international sanitary and phytosanitary standards.) Strengthening development programs which aim at improving the production and trade capacities of developing countries in the sector of basic commodities would not only benefit poorer countries given the high share of agricultural products in their exports but would also have more global effects such as boosting worldwide economic development and food security. In fact, improved sanitary and phytosanitary capacity in developing countries supports sustainable economic growth, poverty reduction, food security, and environmental protection.

A Partnership and Cooperation Agreement for Agricultural Commodities

The criticism of the Washington Consensus and of structural adjustment programs calls for new thinking on development and for a new development-based international consensus – or in WTO’s Director, Pascal Lamy, words, it is time for a “consensus on making trade work for development” (Lamy 2006). But what could be the concrete translation of such a new consensus on development in the commodities sector? A partnership and cooperation agreement on commodities in the framework of a renewed

international architecture would be a major step towards meeting the Millennium Development Goals concerning food security and economic development.

Regional Trade Integration: A Necessary Prerequisite

According to a World Bank report (World Bank 2012a), regional integration can contribute enormously to food safety. However, regional integration is still almost nonexistent in developing countries, and cross-border trade within the African region represents less than 10% of its total trade exchanges. The report even notes that it is easier for Africa to trade with the rest of the world than with itself.

Regional trade integration therefore needs to be deepened – especially in Africa – in order to avoid trade misappropriation (Rakotoarisoa 2011): as long as trade barriers remain among countries within the region, trade flows risk being diverted away and revenue and employment potentially lost. These losses could weaken the regional agricultural sector when the latter could have been an efficient and reliable supplier had the intra-regional barriers not existed. For some agricultural products, regional partners sometimes face much higher applied tariffs than outside suppliers. Many nontariff barriers still exist in the different African regions (Koroma et al. 2009) hindering the free flow of trade. In a report published in December 2005, the FAO stressed that “for developing countries as a whole the greatest potential gains from agricultural liberalization will depend not on reform of the agriculture support system in OECD countries but on reforming their own trade policies, which would encourage greater trade between them” (FAO 2005).

Africa does indeed have the means to produce and supply enough food to feed its population (World Bank 2012a), but this potential is not exploited because farmers are confronted by multiple trade barriers. Among these, many obstacles can be mentioned: the poor general state of infrastructure and roads especially, high transport costs, and the unpredictability of trade policies. The liberalization of intra-regional trade is

therefore crucial in a context of rapid urbanization and dramatically increased demand for foodstuffs.

The Objectives of a Multilateral Agreement on Agricultural Products

In November 2011, the Cannes G20 summit observed: “We stand by the Doha Development Agenda (DDA) mandate. However, it is clear that we will not complete the DDA if we continue to conduct negotiations as we have in the past” (§ 66 of Final Declaration of the G20 Cannes Summit). It is therefore necessary to review agricultural trade negotiations in terms of both framework and content.

Given the issues at stake concerning agricultural commodities and to provide crucial support for importing countries, it would be desirable for the international community to recognize a secure and uninterrupted access for agricultural commodities in exchange for better organization of the commodities market.

However, launched since 10 years ago in the WTO, the Doha Round is blocked and undermines the chances of concluding a multilateral agreement ambitious, comprehensive, and balanced. In the ongoing discussions on how to overcome the current deadlock in the Doha Round, the idea of using plurilateral agreements is increasingly discussed.

According to the WTO, there has been an increase in the number of preferential trade agreements (PTAs). Over the past 20 years, their number has more than quadrupled, with nearly 300 today PTAs in force (WTO 2011).

Plurilateralism must be rehabilitated because it is less harmful than the “minilateralism.” In particular, it remains under the control of the multilateral organization, which de facto is not the case of bilateral agreements. The prospect would be to encourage countries to join gradually this type of agreement to “multilateralize” it after. Obviously, a plurilateral agreement on agricultural products should be perceived not as a rule ideal but as a safeguard, a blessing in disguise.

Reaching a (plurilateral) agreement on commodities, based on the model of a partnership and cooperation agreement and under the aegis of the WTO and the UNCTAD, would enable to

strengthen international cooperation on the management and trade of commodities. This agreement would not be aimed at trade promotion; it would focus on food safety and agricultural development through trade.

A (plurilateral) agreement on agricultural commodities should thus include a development aid component with funding provided for producing countries to, among other things, increase their production and trade capacities. It would consist in:

- Better integrating commodities in aid for trade strategies
- Supporting international initiatives aimed at strengthening the capabilities of the poorest countries to comply with international standards (SPS) but also striving to encourage their involvement in standard development
- Encouraging commodity processing in poor countries as it is an important source of added value by eliminating the adverse effects of tariff escalation for commodities processed by LDCs
- Supporting the economic organization of production and supply chains

The Cannes G20 summit recognized the importance of innovative funding mechanisms for development. The idea is to introduce a tax on the financial sector designed to boost a coordinated development policy. In the agricultural sector, innovative funding could have a considerable impact on food safety and the economic development of poor countries.

Indeed, agricultural commodities markets have become increasingly financialized (UNCTAD 2011a): commodity derivatives, which were traditionally considered as hedging instruments, are now seen as financial investments and are the object of a huge volume of transactions. As such, they are sometimes completely disconnected from the reality of commodity trade. Each year, on the Chicago stock exchange, the equivalent of 16 times the production of corn and 8 times the production of wheat is traded on the derivatives markets.

Therefore, could we imagine the introduction by the international community of a tax, even

minimal, on financial transactions related to agricultural commodities? The goal is not to limit financial transactions as they are an important source of liquidity but to fund agricultural development projects aimed at boosting infrastructure and strengthening the production and trade capacities of poor countries. Once again, the idea is not to counter the market but to, just as in the case of trade, accompany it and adjust its rules.

An International Framework to Secure Trade of Agricultural Products

More than trade liberalization, on which the Doha negotiations have stumbled, the major aim of the multilateral system should be to regulate and update the rule of law. The WTO must contribute to judicial safety and to the predictability of the trading framework. Even though agricultural products represent only 7% of world trade, two thirds of all the countries in the world are net importers of foodstuffs, and only a third are net exporters.

As such, a (plurilateral) agreement on agricultural commodities should be conceived as a framework for securing agricultural trade in order to ensure the supply of commodities for importing countries. Such an agreement should therefore be conceived as:

- A partnership and cooperative agreement combined with a development aid program in the field of agricultural commodities
- An international framework to assure trade in agricultural products achieved through the progressive phasing out of custom duties and quantitative restrictions on trade of products originating from signatory countries as well as through the prohibition of unfair trading practices
- The recognition of the importance of non-trade concerns in agriculture such as social and environmental issues (food safety, land tenure security, and the multifunctionality of agriculture)

Contemporary agricultural and food global relations have profoundly changed due to, in particular, the risk of a structural imbalance between supply and demand of agricultural products, a

growing demand for food and raw materials in emerging economies, the necessity to take into account global climate change, and the related increased politicization of the supply issue. Given the scarcity of agricultural raw materials and mineral, governments are rediscovering the political necessity to secure their supply management (e.g., exports restrictions and taxes in Russia and China). The structure of agrifood trade has also considerably changed since the 1980s. Whereas trade used to be heavily influenced by states, agricultural commodities markets are now increasingly privatized and managed by agribusiness industries.

To what extent could the current international architecture distance itself from zero-sum competition and tend instead towards positive-sum global coordination in the agricultural sector? Though it is crucial for the international community to recognize safe and continuous access to commodities for importing countries, it also desirable that, in exchange, agricultural products' markets be better organized for the benefit of exporting countries.

The producer has always had to make a trade-off between market expectations and desired income from his/her work. It is therefore necessary to secure his/her income through contractual arrangements. Knowing that he/she is going to be able to sell his/her agricultural production at a guaranteed price is a necessary, if not existential, condition for the producer. Why not, then, encourage the development of a legal and economic framework for such a purpose: a supply contract would be the legal instrument which would establish the transaction between the importer (state or industry) and the exporter (state or industry) and through which the former would commit to be supplied by the latter on a continuous basis or for a determined period of time and a financial consideration based on indexed or fixed prices. Given the ever closer worldwide ties resulting from trade globalization and from the increasing importance of non-state actors, the main stakeholders in the global commodities' supply chain should collaborate more efficiently in order to find some win-win solutions – which should be both efficient and sustainable – for these various, and now global,

issues. A multi-stakeholder partnership on commodities similar to the one established for mineral resources (the *Extractive Industries Transparency Initiative, EITI*) should be established. The EITI was launched in 2002 at the World Summit on Sustainable Development with the goal of coordinating public and private sector activities related to the exploitation of natural resources.

Given the tensions and uncertainties related to agricultural products markets – illustrated by the “land-grabbing” phenomenon, for example – international governance is necessary in order to reconcile trade necessities and ethical imperatives. The 2008 food crisis and rising food prices in 2011 led to a skepticism more marked towards the global market. Some states have concluded that they could no longer rely on the international market for grains for sustenance. The scramble for farmland (land grabbing) in Africa and Latin America is a sign of distrust in global markets and will be the source of future geopolitical tensions over access to resources “rare” increasingly coveted. Commodities will be tomorrow the cause of international crisis.

In the majority of raw material-producing countries, the development model based on natural resources does not ensure fairness nor does it stimulate development. Governance of commodity trade still remains to be tackled. A (plurilateral) agreement on commodities, under the auspices of the WTO and UNCTAD, should therefore be based on the classic principle of states’ economic interdependence: in exchange for better organized commodity trade, producing countries would commit themselves to guaranteed supplies for consuming countries. The 2008 and 2011 food crises have highlighted the dangers and disruptive effects of export restrictions. Agricultural basic commodities should no longer constitute the cause of international crises. They should be an important factor of economic cooperation between rich and poor countries and not a battleground.

Summary

In the twenty-first century, agriculture remains a fundamental instrument of sustainable development

and poverty reduction. Nonetheless, continued worldwide food supply problems reveal weaknesses in the model of world governance we have inherited from the past. States and world actors should thus organize a new global network that facilitates the coordination of worldwide trade and agricultural policies in order to let trade truly benefit development. Commerce is vital, because it is the foundation of economic life, and without exchange, there can be no progress or economic development. The challenge is to organize international commerce of agricultural products in a way that improves world governance of agriculture because fighting hunger and making agriculture work in the interests of development demand a minimum amount of regulation of international agricultural commerce. This necessarily requires a new international consensus on development and a reinforcement of development programs in the area of basic agricultural commodities. It also entails taking into account non-trade-related aspects linked to agriculture in order to respect sustainable development objectives.

Introduction

International trade law makes no specific provisions relating to animal welfare. Nation-states are the entities that make commitments to the

governance of trade in international agreements. Within societies, ethical preferences for animal welfare vary in both the level of welfare desired for animals and the specific provisions that are deemed to provide acceptable levels of animal welfare (e.g., types of housing, how animals can be slaughtered, what constitutes cruelty, etc.). The distribution of individual preferences pertaining to animal welfare varies among societies, and national regulatory regimes tend to reflect those broad differences among societies. Differing national standards lead to trade frictions either because (1) countries with what they perceive as higher standards wish to exclude animals and animal products that originate in countries that are perceived as having lower standards or because (2) countries wish to use trade sanctions to induce other countries that have what they consider unacceptable standards to improve their provisions for the welfare of animals.

Ethics in International Trade Law

The major multilateral institution that fosters the negotiation of rules for international trade is the World Trade Organization (WTO). There are also hundreds of preferential trade agreements among regional groupings of countries and bilaterally between individual countries. These preferential agreements could have provisions pertaining specifically to animal welfare, such as those of the European Union, but unless otherwise stated, the discussion below will deal with the WTO agreements. Further, there are multilateral environmental agreements such as the Convention on International Trade in Endangered Species of Fauna and Flora (CITES), which has provisions that regulate international trade in animals and animal products, and standards setting scientific organizations such as the World Organization for Animal Health, which, for example, has been mandated to take the lead internationally on animal welfare, including establishing standards for how trade in animals is conducted.

The current multilateral rules of trade stem from the institutional arrangements put in place at the end of the Second World War to reduce the

sources of conflict among countries. The United Nations was established to reduce political conflicts between nations, the World Bank was established to deal with differences in the level of development between countries, and the International Monetary Fund was put in place to reduce the use of strategic currency devaluations. A fourth institution was negotiated, the comprehensive International Trade Organization (ITO), but was stillborn, primarily because the US Congress was not expected to ratify it (Kerr 2000). One of the ITO's subagreements, the General Agreement on Tariffs and Trade (GATT), was ratified by the US Congress and by default became the de facto multilateral organization making rules for international trade. The GATT came into being in 1947. The GATT was primarily concerned with removing barriers to trade put in place to provide economic protection against imports; almost no provision for ethical objections to trade was included. The only exception was in GATT Article XX (a) which allows countries to impose trade barriers *necessary to protect public morals*. The provision recognized that countries might wish to limit imports of pornography or products not allowed for religious reasons such as pork or alcoholic beverages in Islamic countries. It has not, as yet, been invoked for reasons pertaining to animal welfare.

Part of the reason that provisions for ethically based trade barriers were not included in the GATT was that the economic model that underlies it only expects producers (facing competition from imports) to ask for protection. As protection raises prices for consumers, and hence as they are worse off, they are never expected to ask for protection (Kerr 2010). This model makes sense in the context of economically motivated protection from import competition – the original concern of the GATT. In 1994, the GATT was rolled into the new more broadly based World Trade Organization (WTO). Much of the original 1947 GATT was simply incorporated without change into the WTO. No new provisions on ethics were included in the updated GATT 1994. Any such change would have required consensus from the 100-plus member states of the GATT.

The perception enshrined in the WTO that requests for protection come only from producers in importing countries seeking economic benefits has led to increasing difficulties for the organization since its inception in 1995. Other groups in society are increasingly interested in specific attributes (other than price) of the imports in their markets and sometimes request that their governments put protectionist measures in place. In particular, consumers and environmentalists have been active in requesting protection – one obvious example is genetically modified organisms and food (Kerr 2010). Other examples include products produced using child labor, timber produced in an environmentally unsustainable manner, beef produced using growth hormones, and products from animals killed in ways some consumers consider excessively cruel (e.g., leg hold traps, clubbing of seal pups). The WTO has no mechanism for directly dealing with governments faced with consumer, environmental, or other groups seeking protection (Perdikis et al. 2001). As a result, governments faced with protectionist pressure from consumers or environmentalists in society have often attempted to use other existing mechanisms as justifications for the imposition of trade barriers. In particular, for food safety and the conservation of natural resources, trade barriers are allowed in the WTO and have been areas where contentious consumer or environmental issues have been raised. These ostensive *food safety* or *conservation* issues often embody ethical concerns as well (e.g., genetically modified products or timber from rainforests). Countries may also simply choose to ignore their WTO commitments and put trade barriers in place – countries can impose barriers as long as they are not challenged. As challenges are not costless, in both resource terms and political terms, a challenge may simply not take place. Further, if challenged, a country can choose to ignore an adverse WTO panel ruling and, instead, accept retaliation while keeping its trade barrier in place – as was the case for the EU when the WTO ruled that its import ban on beef produced using growth hormones contravened its WTO commitments (Kerr and Hobbs 2005).

The only direct attempt to have animal welfare concerns incorporated in multilateral

trade agreements at the WTO came from the European Union. In response to ethical concerns of consumers across the European Union, in the 1980s and 1990s, the European Commission had been gradually raising animal welfare standards across the EU. This led to two trade issues. First, while consumers in the European Union could be assured that the animal products they were consuming which originated in the EU conformed to the EU-mandated standards for animal treatment, no such assurances could be provided regarding animal products imported into the European Union. This issue could be dealt with through labeling requirements that would require those exporting animal products to the EU to label their products regarding the animal welfare standards that were applied during their production (Hobbs et al. 2002). Labeling would allow consumers to choose those imported products that they felt had been produced in an ethically acceptable manner.

Labeling is governed by the WTO's Agreement on Technical Barriers to Trade (TBT). Under the TBT, labeling is allowed for new products. It could be argued that animals produced to meet recently introduced higher animal welfare standards constituted new, different, products than those produced using previous (old) animal welfare standards, and labeling could be required. In the negotiations when the TBT was established, however, developing countries feared that allowing trade barriers (including labeling requirements) on the basis of the technology used in production would allow developed countries to erect trade barriers on the basis that less sophisticated technology was employed in production (e.g., cotton shirts produced using handlooms when sophisticated machinery was used in developed countries to produce the same shirt). This was a difficult negotiation, and the eventual compromise that was struck was that trade barriers could be put in place for new products if they are discernibly different, but not based on how they are produced (Isaac 2007). This is known as the production and processing methods (PPM) provision. Animal products such as meat can only be differentiated by the animal welfare standards used in their production – a PPM. They are not

visually differentiable by consumers. Thus, any animal welfare-based labeling requirement for imports was rejected by developing countries. For them, it would have represented the *thin edge of the wedge* for the erosion of their hard-fought achievement of the PPM provision (Hobbs et al. 2002). The PPM provision has been at the heart of much of the controversy regarding the WTO, not only over animal welfare but also environmental sustainability, genetically modified products, child labor, and a host of other issues that have an ethical dimension (Kerr 2010).

The second trade effect of the EU's implementation of stricter animal welfare standards than most of its trading partners was that it increased the costs of producing livestock products in the EU relative to those of import-competing countries – it reduced the international competitiveness of EU livestock producers (Hobbs et al. 2002). Hence, it was not the direct ethical issue that led the EU to push for some recognition of differences in animal welfare regulations in multilateral arrangements dealing with international trade, but it was the competitiveness issue.

At the second special session of the WTO's Committee on Agriculture in 2000, the EU submitted a formal proposal on animal welfare and trade in agriculture calling for animal welfare standards to be addressed by the WTO. The EU put forward several ideas as to how the issue of animal welfare standards could be addressed within the WTO. Their first suggestion was for the creation of a new multilateral agreement on animal welfare. It is unclear whether the EU intended the new agreement to be part of the WTO framework (e.g., like the Agreement on Technical Barriers to Trade) or outside it (e.g., like the CITES).

The second idea was to allow the imposition of a labeling regime pertaining to animal welfare standards for imported foods using products from commercially produced animals as inputs. The EU argued this would enable consumers to make an informed choice.

Third, the EU proposed allowing the provision of compensation to enable producers to meet the additional costs of producing food to EU animal welfare standards – in other words non-actionable

(green box) subsidies. Under the WTO disciplines on subsidies, non-actionable subsidies can be used without the threat of countervailing measures from other members (Meilke and Cranfield 2007). According to the EU, this suggestion was aimed at reducing disparities in competitiveness between countries with different standards and would have no, or at most minimal, effects on trade and production. The EU stated that its three proposals are not mutually exclusive and that some combination of the three would be possible. They conclude their statement by reiterating their aim to “address adequately the issue of animal welfare within the WTO, without conflicting with the long-term objective of trade liberalisation in agricultural and food products” (WTO 2000, p. 3).

The response from other members of the WTO to the EU proposal was emphatic and somewhat predictable. Developing countries responded strongly to all three aspects of the proposal. A number of countries (Uruguay, Bolivia, Thailand, India, Pakistan) took up the theme that, while not indifferent to animal welfare, the priority for their resources was the alleviation of human poverty (Hobbs et al. 2002). This was interpreted as an implicit rejection of the EU's suggestion that there be a separate multilateral agreement on animal welfare. In a similar vein, Argentina and India stressed that countries should be left to set their own standards. Colombia and India rejected the labeling proposal as simply disguised barriers to trade. A number of countries, both developed and developing, suggested that it was up to consumers to decide if they wished to pay for higher animal welfare standards – indicating rejection of both mandatory labeling and the extension of non-actionable subsidies to cover the extra costs. A number of countries, including the USA, rejected any extension of non-actionable subsidies to encompass compensatory payments for higher animal welfare standards, and Argentina explicitly stated that it could not accept any extension of the Green Box list of WTO-sanctioned subsidies to cover the issues raised by the EU (Hobbs et al. 2002).

Some developed countries, however, seemed more willing to accept that animal welfare is

worthy of multilateral discussion. Most did not think the WTO was the correct forum for that discussion, suggesting that a separate agreement outside the WTO might be the way to proceed. Australia, however, suggested that the issue should be left to the World Organization for Animal Health (OIE) (Hobbs et al. 2002). The latter suggestion may have had some resonance with the multilateral community as the OIE was mandated to take the international lead for animal welfare. Since 2005, the OIE's members have developed and adopted eleven welfare standards, eight for animals, and three for aquatic products (OIE n.d.). These include transport of animals by land, transport of animals by sea, transport of animals by air, slaughter of animals for human consumption, and the killing of animals for disease control purposes, among others.

The OIE is recognized in the WTO's Agreement on Sanitary and Phytosanitary Measures (SPS) as an official standards setting organization. This does not mean that WTO members must adopt OIE standards. In the trade context, it means that any country adopting the OIE standards cannot be challenged by other countries that might perceive the standards as trade barriers – they are a *safe haven* (Isaac et al. 2002). As yet, however, there are no direct provisions pertaining to animal welfare in the WTO agreements.

Trade Sanctions

Countries have also attempted to use trade sanctions to induce other countries to alter their practices in ways that would improve animal welfare but justified on grounds of environmental sustainability. GATT Article XX (b) allows trade measure to be put in place when necessary to protect human, animal, or plant health, while Article XX (g) allows them for conservation of natural resources, which some countries have taken to mean marine mammals. The most famous, and controversial, cases involved fishing practices for tuna that lead to the snaring of dolphins in nets leading to dolphins being killed or maimed. In response to the concerns of animal welfare

advocates and others, the USA enacted measure to regulate tuna fishing practices so that such *incidental* takings of dolphins would be reduced (Isaac et al. 2002). These measures were contained in the Marine Mammal Protection Act (MMPA) of 1972 and applied to the US tuna fishing fleet. Other countries, however, continued fishing for tuna in dolphin-unfriendly ways. The MMPA also authorized the imposition of import embargoes on fish caught by nations that do not adequately provide for dolphin conservation. It should be noted that expanding the set of products that could be embargoed beyond tuna was clearly intended as an economic sanction to be used to induce a change in the behavior of other countries (Gordon et al. 2001). In 1991, the US government imposed an import ban on the importation of tuna from Mexico. In response, Mexico requested a GATT dispute resolution panel be struck. The panel, through convoluted reasoning, found in favor of Mexico. According to Spracker and Lundsgaard (1993), the heart of the panel's reasoning was that the import ban could not be employed “in order to regulate production methods that do not affect the character of the imported product” (p. 395) – tuna fishing is a PPM that does not alter the imported product, the tuna. The judgement outraged animal welfare advocates (and environmentalists) and to a large extent soured them on the WTO. Protesters dressed as dolphins became a regular feature of anti-WTO protests. It should be noted, however, that the WTO has no legislative function and only administers what the member states have already agreed to, including the adjudication by dispute panels.

A second Tuna-Dolphin dispute was also brought by the European Union against the USA because the MMPA also authorized a ban on tuna products imported from countries that source their tuna from a country covered by the primary embargo – because the EU imported tuna from Mexico which was embargoed. The panel ruled, among other things, that the exceptions in Articles XX (b) and (g) could not apply to environmental measures whose impact was achieved by forcing a member state to change its policies (Isaac et al. 2002). Again, the ruling was widely condemned

by environmental and animal welfare non-governmental organizations (NGOs). According to Isaac et al. (2002): “The decision of the panels in the Tuna-Dolphin disputes raised serious questions as to the ability of states to further environmental objectives by the use of trade-related measures” (p. 85). As environmental issues are often comingled with animal welfare issues, the same conclusion can be made.

Following the Tuna-Dolphin cases, a further issue where animal welfare concerns were comingled with environmental concerns was brought to the dispute settlement system – what is known as the Shrimp-Turtle dispute. Formally, the issue was dealt with as an environmental issue rather than an ethical issue pertaining to animal welfare. Sea turtles are considered highly endangered under the CITES. The most significant threat to the species arises from incidental capture and drowning caused by shrimp harvesting operations. In response to domestic pressure from animal welfare and environmental groups, in 1989, the USA mandated that all shrimp trawlers fishing in waters likely to contain sea turtles, no matter what their country of origin, be equipped with Turtle Excluder Devices (TEDs) (Isaac et al. 2002). Contained in the legislation was the requirement that the importation of shrimp or shrimp products be prohibited if harvested using a fishing technology that could have a deleterious impact on the sea turtle population.

In response, India, Malaysia, Pakistan, and Thailand requested a WTO panel to determine if the US measures violated the rules. The USA countered that the measures should be allowed under Article XX (b) and (g) exceptions. The dispute went through a long process of panel deliberations and appeals (Isaac et al. 2002). Initially, the panel ruled against the USA, and as a result, protesters dressed as turtles joined those dressed as dolphins as a feature of anti-WTO protests. In an appeal judgement, however, the US measure was accepted in principle as being eligible for Article XX exceptions, but the way the USA had implemented its measure was not consistent with WTO obligations (Isaac et al. 2002). This was judged to be a major victory by legal scholars interested in environmental issues.

The threat of imposing trade sanctions has been used to good effect in other cases where ethical animal welfare issues and environmental issues are comingled. The mere threat of trade sanctions cannot be taken to a WTO dispute panel. One example of the effective use of the threat of trade sanctions has been in the regulation of fishing and, in particular, whaling in international waters. Domestic legislation in the USA – a number of laws grouped around what is known as the Pelly Amendment (Gordon et al. 2001) – gives the US President the discretion to impose trade sanctions on imports of fish from countries not complying with the conservation and management standards embedded in a number of US laws. The USA first used the Pelly Amendment to threaten Denmark, Norway, and West Germany over those countries’ continued fishing of Atlantic salmon. The threat was effective and led to an agreement in 1976 to end the high seas fishing of Atlantic salmon (Gordon et al. 2001). The Pelly Amendment’s ability to threaten trade sanctions has also been used with great effect, and repeatedly, to bring countries into compliance with the International Whaling Commission’s (IWC) restrictions or bans on whaling – either by inducing countries to join the IWC or by complying with its ban on whaling. Gordon et al. (2001) report that, at various times, Japan, the Soviet Union, Chile, Peru, South Korea, Spain, and Taiwan were induced to alter their practices when threatened with trade sanctions on their fish shipments to the USA. Other countries, however, weighed up the cost of potential sanctions and chose not to alter their practices.

Strategic Use of Trade Barriers and Trade Sanctions

Unless a trade partner objects by asking for a dispute panel, a country can impose trade bans or other trade restriction for animal welfare reasons. One example is the EU ban on imports of seal products. In September 2009, the European Union announced a virtual ban (with a few exceptions) on the import of seal products. Canada is the world’s major producer of seal products. Canada

(and Norway) first sought consultations with the EU through the WTO; when those failed, they asked for a formal dispute settlement panel. They had the option of not seeking a dispute panel and accepting the ban. The decision to initiate a dispute is a complex calculation. Formal dispute settlement is expensive and time consuming. Further, even if the EU were to lose the case, it could choose not to comply with the WTO ruling – as the EU did in the case of its ban on imports of beef produced using growth hormones (Kerr and Hobbs 2005). Of course, non-compliance can lead to retaliation being authorized, but the extent of the retaliation is limited to the value of trade lost. The EU may have done a calculation that can easily absorb the cost of retaliation in the case of seal products. Canada and Norway can also do the calculation. In that vein, it is interesting to note that Namibia, another seal product producer, did not join the dispute, choosing instead to accept the economic cost of the ban. While the dispute is going forward at the time of writing, this was not a forgone conclusion at the time the ban was imposed. In any case, the economic impact of the ban for Canada and Norway will continue at least over the period when the dispute is being heard. This is the first time a dispute panel has been asked to decide directly on the legitimacy of a trade barrier imposed for ethical animal welfare reasons.

Multilateral Cooperation

Disputes are an inefficient and not particularly efficacious means of altering public policy. A better mechanism is to obtain multilateral agreement on appropriate public policy. One example where this has been accomplished in the case of ethical animal welfare concerns (although again comingled with environmentally based conservation concerns) is the CITES. In the CITES, countries have come together to, among other things, establish rules of trade that support the objective of preserving endangered species. The CITES trade provisions may, in fact, not be compliant with some WTO provisions, but due to widespread acceptance of the CITES, there has

been no WTO challenge, nor is there likely to be one (Isaac et al. 2002).

Summary

The multilateral system for international trade as embodied in the WTO, as yet, takes no direct account of ethical animal welfare concerns in its rule-making or jurisprudence. Some preferential trade agreements – such as the EU – have included animal welfare provisions. Animal welfare issues are often comingled with environmentally based animal conservation measures, and a number of clarifications regarding the legitimacy of trade measures have been sought through the WTO dispute settlement system. The results have often disappointed those advocating the use of trade restricting measures to encourage stricter animal welfare standards. Countries have, however, at times, used trade measures to advance animal welfare objectives. The CITES is an example of multilateral cooperation in establishing trade policy to achieve ethical objectives outside the WTO.

Trade Policies and Organic Food

GMO-free; Hormone-free; Natural food; Organic agriculture

Introduction

Organic foods are produced using farming methods that may be less harmful to the environment while also leading to foods that are better for human health. Many environmental ethicists who believe that there is a moral obligation to protect the environment may view organic food as more sustainable and thus ethically superior to conventional food (Scialabba 2007; Byerlee and Alex 2005). Some scholars believe that access to safe and nutritious food is a human right seeing organic production as a viable means to achieve this right (Altieri 2009). Attributes such as healthiness and sustainability are invisible to consumers of organic products. Organic foods are differentiated from conventional alternatives because they are produced through different processes (characterized by crop rotation, absence of synthetic fertilizers, and biological control of pests rather than chemical treatments) as opposed to having different physical attributes. In the absence of information that reliably communicates these desirable characteristics, organic foods can only compete on price, and as they are usually more expensive to produce, there will be little incentive for markets to form. Setting up standards and a system to label or certify organic foods can help consumers in making an informed choice. Since countries may differ in how they define standards and certify organic foods, there is a potential for trade conflicts.

Organic Food Standards

Organic food standards determine which products can legally be labeled as organic. According to the International Federation of Organic Agricultural Movements (IFOAM), the market for organic food is confronted with hundreds of national government and private standards, as well as a number of global certification and accreditation systems. Examples include the US National Organic Program (USNOP) and the part of the Japanese Agricultural Standard (JAS) pertaining to organic agricultural products. Global standards include IFOAM standards, the Codex

Alimentarius Commission guidelines maintained by the Food and Agriculture Organization (FAO) of the United Nations, and at a regional level, the European Economic Community's (EEC) Council Regulation 2092/91 (Schmid et al. 2007). Some of the private standards include BIO AUSTRIA, Bio Suisse (Switzerland), Naturland (Germany), and the Soil Association (UK) (Setboonsang 2008). The EEC guidelines are considered the minimum standards with which all EU member states have to comply. If required, any state can have a national or private standard with more detailed requirements, depending on local or regional concerns (Schmid et al. 2007).

Heterogeneity and Trade Conflicts

A detailed review of the differences between the EEC and selected national and international organic standards is reported in an article by Schmid et al. (2007). National standards from 16 European countries, and the United States, and international standards – IFOAM Basic Standards, Codex guidelines – were compared with those of the EEC. The standards differed in terms of their organic labeling schemes, recommended crop and livestock production methods, processing techniques required for organic produce, and environmental protection provisions.

There are differences in the way the US certification system and the EEC regulations handle the question of whether a food can be labeled organic if it is made from less than 100% organic ingredients. The EEC regulations apply to livestock feed, while the Codex does not include provisions for organic feed (Schmid et al. 2007).

Standards related to organic crop and livestock production (such as the use of fertilizers, manures, crop rotations, and animal stocking densities) also vary to a considerable extent. For instance, though most of the EU member states require that seeds and vegetative propagation materials be of organic origin, they differ in the way seeds from conventional sources are allowed when organic seeds are not available. A study by Thommen and Schmid (2006) shows that the areas cultivated with nonorganic cereal seeds were much higher in Belgium, Italy, and Spain compared to other member states because they had different criteria

for accepting the use of nonorganic seeds. Because organic seeds are more expensive, these countries may have had a competitive advantage as a result of these differences. EU regulations include limitations on the use of livestock manure (170 kg of nitrogen from manure per ha/year of agricultural area used) and the export of surplus manure, while Codex and USNOP do not set any limitations for nitrogen use. Some private standards such as Naturland (Germany) and Bioland (Germany) have even tighter regulations allowing only 112 kg N/ha. Such differences can lead to trade distortions by lowering costs for firms in countries that have set looser restrictions on manure use. Schmid et al. (2007) note that several countries have more detailed requirements for crop rotations and tighter restrictions on fertilizer use.

Regulations on pesticide contamination and contact with genetically modified organisms (GMOs) also vary between countries. To prevent cross fertilization between organic and GMO crops such preventive measures as windbreaks or buffer zones may be required. For instance, USNOP requires buffer zones to prevent contamination from conventional farms, but the EU does not have such provisions. Countries in which such measures are not required will have a cost advantage relative to those in which they are required. Five private standards allow greenhouse production but with limits on the use of artificial light and heating systems to reduce the consumption of nonrenewable resources. Such restrictions could represent a particular burden on producers of organic products in the colder, northern European countries compared to the costs in the central and southern Europe.

Although the global organic market size has increased threefold since 2000 (Willer and Kilcher 2012), most of the food produced and consumed around the world comes from conventional agricultural systems. Alroe et al. point to negative externalities such as soil and water degradation and the loss of biodiversity that may arise from both conventional and organic food systems. Organic standards may require attention to some of the negative effects, but in many cases, they do not include restrictions related to critical aspects

of soil, water, and biodiversity conservation (Alroe et al. 2006).

Harmonization and Equivalency

Although there are both national and international organic standards, there is no clear mechanism for resolving trade disputes that might arise from different organic standards. The WTO does not have specific provisions on organic food standards (Daughjerg 2012). Trade conflicts due to differences in standards can give rise, however, to cases that could lead to complaints under the WTO technical barriers to trade (TBT) provision. For example, some delegations to the WTO expressed concern about a draft organic certification procedure under discussion in Korea requiring that organic foods be certified by Korean authorities or by agencies approved by the Korean government (WTO 2012). Several delegates objected that the draft provisions did not include ways to establish equivalency with standards in other countries, and in the absence of a means to establish that other standards are equivalent to those in Korea, the Korean standards would be inconsistent with Korea's WTO obligations under the TBT agreement.

As the Korean example shows, the standard procedure for international trade in organic food involves agreements between nations that their standards are substantially equivalent. Such agreements allow foods certified as organic in one jurisdiction to be sold as organic in another. An alternative to equivalency agreements would be complete harmonization of organic standards so that a single set of standards could be applied worldwide (Schmid et al. 2007). Because of the difficulty of reaching agreement on a single set of standards and the lack of an international enforcement body, equivalency agreements have been the most practical approach to reconciling different organic standards so that organic products can be traded.

The equivalency agreement between the United States and the EU offers a good example of how such agreements are structured. This agreement, the "Organic Equivalence Cooperation Agreement" adopted on February 15, 2012, specifies that standards in the US National

Organic Program (USNOP) will be considered as equivalent to the EU Organic Program, thereby allowing organic goods certified by the appropriate authorities in each country or region to be marketed as organic in the other (Bendz et al. 2012). Traded organic products must have an "organic export certificate" showing the location from which they come and the agency providing the certification as well as assurances that all relevant standards have been met. The information provided with these products insures that consumers can be confident that the organic foods being purchased are, in fact, produced and handled using recognized organic methods.

The agreement includes specific requirements regarding the origin of the products. Organic products certified in the EU and the United States but not produced, processed, or packaged in these countries cannot be exported under this agreement. For example, Ecuadorian bananas certified under EU regulations cannot be directly exported from Ecuador to the United States. The agreement is to be reassessed after 3 years with a view toward achieving greater harmonization of the two sets of standards (Bendz et al. 2012). Some of the areas for future discussion include differing requirements for veterinary treatments and handling of manure and fertilizer.

Ethical Issues in the Trade of Organic Foods

So far, trade in organic foods does not appear to raise a lot of ethical issues. Equivalency agreements allow trade in organic foods which, in turn, means that over time organic production and consumption is likely to grow. Because organic production is generally thought to be less harmful to the environment than conventional production, this evolution can be seen as positive. For some, organic food embodies certain ethical characteristics. For example, IFOAM identifies four ethical principles that define organic agriculture:

The principle of health – organic agriculture should sustain and enhance the health of the soil, plants, animals, and humans as one and indivisible.

The principle of ecology – organic agriculture should be based on living ecological systems

and cycles, work with them, emulate them and help sustain them.

The principle of fairness – organic agriculture should build on relationships that ensure fairness with regard to the common environment and life opportunities.

The principle of care – organic agriculture should be managed in a precautionary and responsible manner to protect the health and well-being of current and future generations and the environment.

Differences in national organic standards may reflect the fact that countries place different weights on the various principles identified by IFOAM (2006). For example, organic standards on antibiotic use in the EU and in the United States may differ because of national variation in attitudes toward animal rights. According to Zanolli (2004), consumers in the EU are concerned not only about the overuse of antibiotics in animals (for them lower antibiotics use implies healthier food products) but also about the welfare of the animals themselves. EU consumers are more likely to feel that the principles of care and fairness should be extended to animals than consumers in the United States. These value differences may be obscured by equivalency agreements that require all certified foods to be treated as if they met local standards.

Some might suggest that organic food is problematic. If resources are directed away from conventional food for use in organic production and if the amount of food that can be produced from a unit of productive resources is less with organic than conventional, expansion of organic may not be a good thing. Organic production is currently pretty small relative to conventional food output, and it seems unlikely that organic will ever replace more conventional production methods. If expanded organic production were to lead to food shortages, prices would increase providing an incentive for producers to switch back to conventional methods to increase output. Short of some kind of absolute authority that could override market forces and make organic mandatory, it is unlikely that there would be a big problem of this nature.

Trade Implications for Developing Countries

Though Europe and the United States account for around 90% of the global sales of organically certified products, the domestic supply of organic products in these countries has been unable to keep pace with the growing market demand (Barrett et al. 2002; Dimitri and Oberholtzer 2009). For instance, in the United States, inadequate availability of inputs for organic dairy and livestock production is an important reason for retail shortages in organic dairy and meat products (Oliver 2006). Organic food shortages in developed countries represent opportunities for developing countries to produce and export organic products. Because much agricultural production in developing countries is done with few or no chemical inputs, it may be easier for growers in these areas to switch to completely organic production. To gain access to export markets, however, producers in the developing countries must abide by the international standards and foreign organic certification systems, and compliance with these standards may be costly (Barrett et al. 2002). Setboonsarng (2008) examines the role in developing countries of the IFOAM international standards and some national and private organic standards. He claims that clear organic standards and certification systems may allow producers in developing countries to market organic food in high-income countries, potentially avoiding extensive use of chemical and energy inputs. The expansion of organic production in developing countries could have beneficial effects on the environment while at the same time raising their incomes. Both of these developments are consistent with environmental and development ethics. A joint project known as Global Organic Market Access (GOMA 2012) has been undertaken by the IFOAM, the FAO, and the United Nations Committee on Trade and Development (UNCTAD). A regional subgroup of GOMA is attempting to establish common organic standards among Asian countries.

Summary

Organic food standards are necessary for markets for these products to develop. Without standards, consumers cannot be certain that the foods being purchased really are organic with all the ethical attributes they associate with these products. This is true for both domestic and international markets. Conflicting national standards could impede international trade slowing the growth of organic production and consumption. Because organic food is less harmful to the environment and may have desirable attributes for consumers (e.g., health and taste), mechanisms to coordinate organic certification across international markets are beneficial. The WTO does not have special provisions on organic food standards, but countries are expected to recognize certification equivalency, and these expectations are backed up by the WTO's TBT regulations. Recently the EU and the United States have agreed to recognize each other's standards as substantially equivalent, thereby allowing US certified organic food to be sold in the EU as "organic." Both have agreed to forge a common understanding on various environmental and animal welfare issues important to achieve harmony and facilitate trade. Compliance with international organic food standards and certification systems, though costly, may be beneficial in the long run for developing countries which may have certain advantages in organic agricultural production with positive consequences for both the environment and development in low-income countries.

Genetically engineered crops; Genetically modified crops; Transgenic seeds

Introduction

Transgenic crops have been embroiled in controversies since first taking root, raising a range of questions from their safety to the future of the food system. Today, transgenic crops make up a considerable portion of the planted areas of crops such as soy, corn, cotton, and canola, but find very little adoption in crops like wheat and rice. Grower adoption of transgenic soy happened so quickly in the USA from 1996 to 2006 that by some measures it is often described as the most extensively adopted agricultural technology in human history. While some agricultural sectors and segments of the value chain have benefited from transgenic crop adoption, the technology remains the topic of several ongoing conversations about implications for agricultural sustainability. Before describing these controversies in more detail, the next few paragraphs describe how transgenic crops are made.

The term transgenic is an adjective used to describe an organism with genes that have been moved from one place to another in its genome or from one species' genome to another. The etymology of "trans-" is Latin for the phrase "to cross." Sometimes transgenic organisms are referred to as genetically modified (GM) or genetically engineered (GE); GM organisms (GMOs) are the most colloquial in use, although GE organisms (GEOs) is also commonly used. Some analysts and activists restrict the term transgenic to instances where genes are moved

across species barriers, but it is widely agreed that moving genes within the same species should also be considered transgenic. The technological developments that make transgenesis or genetic engineering possible come with the tools of recombinant DNA technology, which allow plant breeders to move genes around at a scale not possible through conventional breeding. Often, the use of recombinant DNA techniques determines whether or not an organism deserves the transgenic label.

Genetic engineering introduces DNA into the host organism (or new place within an organism) several different ways. This transgenesis is referred to as an event. The most common way is to introduce the DNA with a viral or bacterium invasion into the host's nucleus. This virus or bacteria is what is called the promoter sequence. Transferring genes using a bacterium involves combining the desired gene with a plasmid, which is then carried by an agrobacterium, most commonly *Agrobacterium tumefaciens*. The agrobacterium moves through the cell wall, depositing the desired gene in the host organism. After gene transfer, both the promoter and the desired gene remain in the plasmid. These plasmids are then cultured in a petri dish, and in the case of plants, moved to a greenhouse where it is determined whether or not the desired gene is expressed in the plant's phenotype. This is often done with a marker gene that is attached to the promoter, which when expressed makes it easy to identify which plants contain the desired gene. The most widespread marker genes are those for antibiotic resistance. When applied, the antibiotics kill any cells without the new genes, leaving behind only cells that have taken up the marker gene and promoter. The use of antibiotic resistance genes raises concerns about foods made from transgenic plants because it is unclear whether or not the antibiotic resistance affects human health or confers resistance that could impact human and animal populations. Alternative marker genes include traits of phosphorescence from jellyfish, where the desired trait can be ascertained by exposing the organism to a black light.

Other means of making transgenic plants use nonviral promoters. The particle gun or “gene gun” technique uses gold or tungsten covered pellets coated with bits of DNA that penetrate the cell wall and randomly insert themselves into the hosts DNA. Electricity can also be used to create momentary holes in the cell wall, which allow promoters and markers to be delivered to the nucleus.

This entry describes several ethical issues derived from the interplay between science and politics of transgenic crops. With transgenic crops comes a new biotechnology that allows plant breeders access to an unprecedented pool of genes to work with. At the same time, the technology raises a host of social and environmental questions about property rights, ecological viability, and the role of public sector plant breeding research. The first section explains the emergence of transgenic plants out of the labs and into the fields as well as the scientific controversy to understanding their early research, development, and deployment. The second section introduces the views taken by biosafety ecologists about their potential risks to the environment. The third section summarizes a few of the social implications from transgenic plants. The final section describes the current extent of transgenic crop deployment today as well as future deployment scenarios.

The Evolution of Transgenic Crops

The first product of recombinant DNA technology destined for open-air use and to receive considerable public attention was the deliberate release of the “ice minus” bacterium (*Pseudomonas syringae*) developed by University of California plant pathologist Stephen Lindow (Krimsky and Plough 1988). The goal of the project was to spray potatoes near Tule Lake in Northern California with an “ice-nucleation active” bacterium to inhibit the formation of frost on the plants. It was claimed that this could have important implications for staving off early season frosts, with potentially tremendous saving to growers. While not a transgenic crop per se, the treatment of the ice minus bacteria by regulatory officials would become the basis for future field trials of

transgenic crops, which would dominate GEO deployment over the following two decades. The unintentional escape of the ice minus GEO led to concerns about the impact on ecosystems adjacent to the fields where it was introduced, as well as possible implications on global weather patterns. This aroused local reactions in the Northern California cities of San Francisco, Berkeley, and Oakland, which included moratoria and outright bans on outdoor experiments.

The National Institute of Health (NIH) Recombinant Advisory Committee eventually approved field trials of the ice minus bacteria. Activist Jeremy Rifkin of the Foundation on Economic Trends obtained a court injunction to stop the release, arguing before the court that the experiment posed an environmental hazard and that there were no adequate containment protocols in place. Rifkin argued that the NIH was required to prepare an Environmental Impact Statement under the National Environmental Policy Act to evaluate environmental impacts because a federal agency made a decision that could impair the environment.

The fallout from the controversy led to a new round of discussions about how GEOs should be regulated, ultimately leading to a decision by Congress in 1985 to regulate them through the existing regulatory system. Under what is known as the “Coordinated Framework,” the Food and Drug Administration (FDA) evaluates food safety concerns; the Environmental Protection Agency (EPA) oversees concerns about toxicity from mobile plant tissues like pollen and root exudates, as well as issues related to insect resistance to plant incorporated pesticides; and the Department of Agriculture’s Animal and Plant Health Inspection Service oversees problems related to increased weediness and biological invasion. Many activists and ecologists saw the Coordinated Framework as an effort to manage GEO introduction instead of regulate it.

Ecological Risks from Transgenic Crops

Genetically engineered organisms in general, and transgenic crops in particular, have always raised

questions about how they will impact ecological processes both within and outside farmer fields since the first plans to release them in the early 1980s (Altieri 2000). The Ecological Society of America (ESA), a professional society of ecologists and conservation biologists, evaluated some of the potential ecological and environmental hazards associated with introducing GEOs into the environment in 1985. They noted that the products of genetic engineering and recombinant DNA technologies posed no new classes of ecological hazards. But the novelty of the new technology warranted regulatory oversight, because there is the potential for more extreme and uncertain ecological hazards. The ESA scientists that signed onto that statement strongly advocated a robust system of containment to prevent escape of the transgenes into the environment. For plants this meant controlling seed dispersal and possibilities for inadvertent cross-pollination. They also argued for early ecological risk assessments of GEOs to ensure they did not pose significant impacts to native flora and fauna before release. However, early planning for ecological risk assessments face considerable challenges such as trade secrets and intellectual property protections that make transparency difficult.

Ecologists' opinions on the risks from GEOs vary widely and are typically organism and context specific (Snow et al. 2004). Some GEOs may pose greater threats to the environment, than others. GEOs may suffer greater fitness consequences from having their phenotypic expression altered in ways that make them more dependent on human intervention to reproduce in areas outside agricultural production. More holistic frameworks urge an approach to evaluating the risks of biotechnology recognizing that uncertainty, complexity and incomplete knowledge must factor into any regulatory approach including post-release monitoring to more comprehensive ecological risk assessments.

Loss of Plant Genetic Diversity

One important impact from transgenic crops is the loss of genetic diversity through gene flow – the transfer of genes from population to another (Letourneau and Burrows 2002). Gene flow may

have consequences to genetic diversity through outbreeding depression or genetic swamping where there are sexually compatible wild relatives near or in farm fields where transgenic crops are planted. In outbreeding depression, the fitness of the offspring is lower than the originating plants. In the long run, these plants will not be successful competitors and risk extinction or extirpation. Outbreeding depression would occur if short-term fitness advantages favor the increased presence of the transgene in the population but with long-term fitness consequences over time (e.g., reduced fecundity, increased disease susceptibility). Genetic swamping occurs when there is a high ratio of transgenic plants to the wild relative. In effect the wild relative is swamped with genes from the transgenic crop field, compared to other wild relatives. Genetic swamping would most likely occur where the receiving plants are relatively rare and exposed to high rates of hybridization. Both of these processes occur with conventionally bred crops, but risks may be heightened with transgenic crops.

Areas most susceptible to concerns about loss of genetic diversity are in the Vavilov centers of genetic diversity and crop domestication (Fowler and Mooney 1990). These centers serve as sources for genes used in breeding programs, and at times throughout recent history have been critical to efforts to combat disease in conventional crops with the corn blight of the early 1970s as a prime example. After the blight wiped out significant portions of successive corn crops, researchers returned to Mexico, an important site of corn domestication, where they were able to find genes for resistance to the disease in the wild relative *teosinte*. The loss of crop genetic diversity is often raised in the controversy over transgenic maize in Mexico, where both small farmers and international research institutions depend upon the diversity of wild relatives and landraces for plant breeding.

In 2001, a University of California at Berkeley professor and his graduate student tested maize landraces grown in Oaxaca, Mexico, the center of crop diversity for maize, and found the presence of patented transgenes despite a moratorium on transgenic maize (Quist and Chapela 2001). Their

study found not only the presence of transgenes in maize landraces but also suggested that the transgenes inherited did not exhibit the stability ensured by the crop's developers and patent holders. Their initial findings were published in a brief article in the journal *Nature*. Shortly after publication, the journal came under fire from the scientific community, particularly those supportive of the life sciences industry and from within the discipline of molecular biology. *Nature* retracted the article, questioning the researchers' methodology and interpretation of evidence. When data were subsequently submitted supporting the findings, *Nature* refused to publish them, to retract the retraction, or to provide a forum to pursue earlier editorial commentary. Despite concerns that transgenic crops may pose threats to plant genetic diversity, the *Nature* controversy continues to be framed as one of academic practice and integrity. The point that transgenic traits were found in Mexican maize landraces, a Vavilov Center of crop-wild diversity, seemed to be lost in the debate. Opponents were noticeably silent about the permeability of the food and seed systems in response to questions from NGOs, indigenous groups, and ecologists about the adequacy of regulatory institutions to control the deliberate introduction of transgenic crops in areas of critical plant genetic diversity.

Herbicide Resistance, Increased Weediness, Superweeds

Another agro-ecological risk from transgenic crops comes from the use of traits for herbicide tolerance. These traits are attractive to farmers because instead of costly weeding techniques, growers can spray herbicides after their crop has emerged from the seed. Without genes for herbicide tolerance, this would damage the crop. But herbicide tolerant crops will not die when exposed to the herbicides. The use of herbicides this way has increased the amount of no-till weed control in crops such as soy.

However, widespread use of herbicide-tolerant crops such as RoundUp Ready™ and Liberty Link® varieties has led to the evolution of resistance to herbicides like glyphosate and glufosinate in weeds, either as a result of increased

exposure to the herbicide which would select for tolerance over time or as a result of the horizontal transfer of the trait to weedy relatives of crops (National Research Council 2002). These have become known as “superweeds” in the public discourse. Eventually herbicide tolerant crops could alter the mix of herbicides applied as some become ineffective due to overuse, which could result in greater levels of overall environmental harm. Since herbicides differ in acute toxicity and persistence, loss of some herbicides may be detrimental to the environment overall. Moreover, the herbicide RoundUp is used in ecological restoration, so increased weed resistance could force restoration managers to use more toxic herbicides.

Insect Resistance

The introduction of transgenic crops also raises concerns about insect resistance. The naturally occurring microorganism *Bacillus thuringiensis* (*Bt*) has been used as a pesticide for several decades. When ingested by many species of Lepidoptera, and some Coleoptera, it crystallizes and blocks the passage of food into the stomach of effectively killing them. Its rapid degradation when exposed to UV light keeps it outside of the EPA's oversight allowing it to be widely used in powdered form by organic farmers. However, many studies have shown that *Bt* resistance can evolve rapidly in agroecosystems (National Research Council 2002). Incorporating the genes that produce the *Bt* endotoxin into plants and subsequently planting them on such a large scale could, unless properly managed, hasten the evolution of resistance, with implications for both organic and conventional farmers.

Currently, industry uses a high dose-refuge model to suppress the evolution of resistance in Lepidoptera. They argue that the high dose of *Bt* will kill most of the pests and that the alleles that develop resistance will be “diluted” by the presence of a non-*Bt* refuge harboring *Bt*-susceptible Lepidoptera (Alstad and Andow 1995). However, this argument rests on two assumptions. The first is that *Bt* resistance is a recessive trait; the second is that farmers actually plant the refuge. On the latter point, it is worth noting that the responsibility for employing the high-dose refuge model is

shifted from the seed developer to the farmer in the technology use agreements often required to buy transgenic seed.

Changes to Chemical Use Regimes and Impacts to Biodiversity

The impacts of transgenic crops on biodiversity from changes in farming practices may be to the detriment of the biodiversity near and in farms. In October 2003, the Royal Society of the UK published its findings from farm scale evaluations (Andow 2003). Two out of the three crops studied demonstrated an association between transgenic crops and practices harmful to wildlife as well as a tendency to decrease biodiversity. The report attributed the impacts to changing in spray regimes of herbicides, finding that wildlife adjacent to GE crops were subject to increased exposure to agrochemicals such as atrazine, pointing to a significant difference in agronomic practices associated with GE and conventional varieties.

Impacts to Nontarget Organisms

Nontarget effects of GE crops could threaten both biodiversity and agronomic practices such as integrated pest management. Plants engineered to produce toxins in mobile tissue parts such as pollen pose threats not only to susceptible species that enter into areas where the crop is grown but also to the adjacent field margins where the pollen may drift as in the monarch butterfly controversy. Researchers from Cornell University suggested that *Bt*, *Bacillus thuringiensis*, which drifted onto milkweed growing in adjacent to fields of *Bt* corn, increased the mortality rates of monarch larva (Letourneau and Burrows 2002). At the time, the EPA did not consider nontarget organisms as an area to explore in risk assessment. Further research revealed that the impacts of *Bt* corn on monarch butterflies was affected by the amount of *Bt* expressed in the pollen itself, and industry soon eschewed *Bt* varieties with high levels of *Bt* in corn pollen.

Toxic mobile plant tissues may impact soil biota as well. Shielded from UV rays, *Bt* has been shown to accumulate in the soil through the root exudates of transgenic plants. The impact of dosing the rhizosphere with the *Bt* endotoxin has

not been evaluated for consequences to nontarget soil organisms or to soil health. Beneficial insects used in the biological control of pests are also subject to nontarget effects. One study suggests that the green lacewing, an insect beneficial to farmers because it eats the same pest that *Bt* is used against, suffers greater mortality rates after consuming *Bt*-fed prey (Letourneau and Burrows 2002).

Viral Resistance

Viruses are known to attack some kinds of plants, and transgenic crops are being designed that are resistance to these viruses. Transgenic crops bred for viral resistance have the potential to create new or more virulent viruses through two mechanisms: recombination and transcapsidation. The former can occur between the plant-produced viral genes and closely related genes of incoming viruses; the latter occurs when nucleic acids from one virus are incorporated into the protein structure of plants. Both can result in viruses that infect a wider range of hosts, demonstrate increased virulence, or lead to a biological resistance “arms race.” Furthermore, some viruses play an ecological role in plant community dynamics. For example, barley yellow dwarf virus resistance has been engineered into cultivated oats to prevent yield losses. But this virus also suppresses invasive wild oats. The transfer of viral resistance here may increase the invisibility of wild oats in natural communities as it alters plant competitive interactions (Letourneau and Burrows 2002).

Ecological Risk Assessment and Biosafety Regulation

Biosafety ecologists agree that ecological impacts are greatly unknown. Ecological risk assessments to date suggest that some organisms pose threats to the environment, while others will suffer greater fitness consequences from having their phenotypic expression altered. A more modest approach to evaluating the risks of biotechnology recognizes uncertainty, complexity, and incomplete knowledge while emphasizing the precautionary principle from post-release monitoring to designing rigorous ecological risk assessment.

Social Impacts from Transgenic Crops

Activists urge that assessments of transgenic crops be accompanied by analyses of the social consequences of these novel technologies. The history of technology adoption is littered with inequality and disproportionate burdens of impacts. Many activists successfully use biosafety as a surrogate for getting at questions about access, control, and development of new technology.

Market Impacts

The most apparent social impact from transgenic crops adoption has been the losses of sales and markets to genetic contamination (Mulvaney et al. 2011). In several cases including the StarLink™ controversy – where unapproved transgenes were found in processed foods – growers were not able to sell their crop because of the presence of transgenic traits. In some instances they also were shut out of future opportunities to sell their crops. In the StarLink example, the USA was immediately blocked from selling corn to Europe, a market they never regained.

Intellectual Property Rights

Patents are the form of intellectual property right invoked to protect the investments in scientific research and technological development made by seed companies to breed and market transgenic plants. Legal battles over patent violations involving Percy Schmeiser, Hugh Bowman, and other farmers against agribusiness giant Monsanto demonstrate how the norms of patent law often conflict with farmer practice. Who owns the crop when patented seed is inadvertently introduced to a field? Should damages be paid if the crop is no longer marketable or seed no longer useable? Some legal scholars contend that common law concepts of nuisance or trespass can be used to settle unintentional movement of transgenic seed into a farmer's field. Others have argued that if seed is not being used for the trait that is patented, for example, if herbicides are not used on herbicide tolerant seeds, that use does not constitute a patent violation. In secondary seed markets, where farmers obtain seed from leftover grain,

should a patent be recognized as abandoned if seed companies do not set up systems at grain elevators to separate common from patented seed? Or are all users of common grain at risk of patent violations should they use the seed admixture? Also related to the issue of protecting patented seed is the use of genetic use restriction technology, colloquially known as terminator gene technology, which renders seed unviable so it cannot be grown.

Farmworkers and Chemical Use

One important benefit from the use of insect resistant crops is the possibility that it could reduce farmworker exposures to pesticides. There has been some research that suggests that farmworker poisonings in China's cotton fields was reduced with the adoption of *Bt* cotton. But more longitudinal studies are needed to ensure that short-term chemical reductions are not offset by increased chemical use in the long run if *Bt* cotton becomes ineffective or chemicals are required to eliminate secondary pests.

Privatization of University Research

Perhaps the most significant impact from the development of transgenic crops is the loss of public plant breeding institutions (Busch et al. 1991; Lacy 2000). As the high-tech costs of r-DNA technologies increase the budgetary needs of plant breeders, there are increasingly partnerships between public institutions and private corporations. While many public plant breeding institutions have historically provided seeds to farmers (Kloppenburg 2004). The entry of private companies and the need to develop patents into university research may make such arrangements an anachronism.

The Extent of Transgenic Crops Today and Future Deployments

Today transgenic crops cover approximately 180 million hectares as of 2015 according to the annual numbers posted by the International Service for the Acquisition of Agri-Biotech Applications. The most widespread transgenic crops are

engineered for herbicide tolerance and for insect resistance – over 98% – though other traits are becoming increasingly more common. The most widespread crop types are soy, corn, canola, and cotton. Other crops grown commercially include papaya. Wheat and rice, two of the world's largest crops in terms of global acreage, still remain in research and development as no transgenic seeds of these crops are commercially available as of 2016.

Controversies on the horizon include the development of crops that are resistant to more toxic kinds of agro-chemicals such as 2, 4 D. One concern is that weeds may become resistant to the chemicals used on first generation crops and be replaced by transgenic crops tolerant of more toxic chemicals. Many new transgenic crops are being grown for biofuels particularly for novel algae and cellulosic feedstocks. Many emerging biocatalysts and yeasts are genetically engineered as well. A number of crops designed for industrial traits are also grown as bioplastic feedstocks. Growing crops to produce pharmaceuticals, fuel, and industrial chemicals will present pollen and seed management challenges, as cross pollination or misplaced seeds could unknowingly transfer genes coding for chemicals that could affect food safety. For this reason some advocate the ban of the production of these chemicals in food crops or crops that can cross-pollinate with food crops.

The global land area dedicated to transgenic crops will continue to grow so long as they do not impact grower sales and if social resistance can be overcome. The challenge for the industry will be to demonstrate that the benefits to growers outweigh any additional seed technology use fees and convince the public of their safety. For scholars looking to understand the implications of transgenic crops on society and the environment, there is now a track record of widespread crop adoption to evaluate. Much of the research to date has been on questions related to r-DNA transfer techniques and productivity of transgenic crops. But there is a growing literature reflecting on the ethical, biosafety, and social implications from transgenic crops that can aid future inquiries.

Conclusion

Transgenic crops will continue to be an area of controversy and topic of conversations regarding civilizations's grand challenges such feeding and energizing a planet approaching ten billion people. The advent of CRISPR technologies portend to blur the categories of synthetic biology, further complicating the governance of these emerging technologies and their associated ecological risks. However, this framework serves as a guide for evaluating the impacts of all crops introduced into the environment, irrespective of the type of breeding used.

This entry explores the evolution of transgenic crops, their ecological risks, and the political economic implications. The introduction explains what transgenic crops are, how they are made, and how they are regulated. The section on ecological risk explores the various categories of risk that biosafety scientists and ecologists have identified to be related to the release of transgenic crops into the environment. The final section describes future directions and ethical challenges for transgenic crops.

Introduction

Trust is important in the food sector. This is primarily because households entrust some of the tasks related to food preparation to food processors. The public is concerned about pesticides, food additives, preservatives, and processed foods

that may harbor unwanted chemicals or additives. After numerous food scandals, consumers expect food processing industries and retailers to take responsibility for food safety. Meanwhile, the food industry focuses on profit growth and costs reduction to achieve higher production efficiency and competitiveness. It means that they introduce innovations, such as new production methods, processing techniques, and additives. Consumers have to delegate the responsibility for ensuring food safety to food producers, retailers, and regulatory authorities who ensure that the foods are safe, healthy, and pose no risks. For consumers, trusting these actors can reduce feelings of uncertainty. It is helpful for companies to be responsible for their activities through transparency and traceability. In turn, the food industry tries to gain consumers' trust by providing objective information, such as ranked brands or labels on food packages.

The Concept of Trust in Food

There are various definitions of trust (Shapiro 1987). The most recurring elements in trust definitions are (1) trust as a set of beliefs or expectations, (2) trust as a willingness to act on those beliefs, and (3) trust as dependency. Trust is related to the task of minimizing risk, for example, for consumers when they choose and use products and services. Anthony Giddens (1990) pointed at the balance between trust and acceptable risk. For understanding trust in food, we can see the link with risk assessment, as well. It results from uncertainty regarding the freshness of the food, its origin, or quality. If the above features are not met, there is a danger of, for example, food poisoning. Nevertheless, people take the risk of eating food that they have not prepared themselves because we all have the need for daily food (Bildtgård 2008). Trust in food is seen as the main component of health creation, well-being, happiness, and pleasure.

There are three theoretical bases for trust in food: emotional, habitual, and reflexive trust. Emotional trust (basic trust) means that people trust somebody because their emotional bond demands it, and not because friends and family

find them as trustworthy. We tend to rely on people whom we know to be competent, rather than the ones we know too little about to judge. They are expected to behave responsibly, honestly, and justly (Sztompka 1999). Habitual trust is based on the assumption that events occurring in the world will continue pretty much as they have before. Trust in food was created and maintained primarily through the habits generated by public ways of thinking. Until this assumption is betrayed, the trust will be habitual and automatic. The consumer does not necessarily reflect on the reasonableness of placing trust in some food brand that they choose or in the chef at a restaurant. Instead, they trust them because nothing has happened so far. Finally, trust in food is reflexive when it is consciously chosen. Giddens (1990) proposed the idea of reflexive thinking that implies that the trust has acquired a conditional character and is associated with active skepticism. It can happen when, for example, there is a food scandal that caused the consumer to start considering a cessation of consumption of a given type of food.

Dimensions of Consumer Trust in Food

The determinants of consumer trust include: (1) demographic determinants: age, gender, education, material status, and family life phase; (2) economic factors: income, price, products, place of sale, and advertising; (3) socio-cultural: family, opinion leaders, and reference groups; and (4) psychological factors: motives of action, needs, beliefs, and attitudes.

The above consumer characteristics in combination with dimensions of trust may contribute to the enhancement of general consumer trust in food. As a core dimension of consumer trust, following constructs can be mentioned: (1) care and (2) openness, which make up the so-called social trust, and (3) competence – being close to the concept of confidence (Poortinga and Pidgeon 2003).

Care is associated with a consumer attitude that is related to the care of themselves. It can mean care of food value about the location of food production; used food ingredients; production environment of food; manufacture date and

expiration date of food; food testing information; the transportation process of food; and the storage environment of food.

Openness indicates the need to find novel solutions, express original ideas, and employ imagination when performing tasks.

Competence is the ability, knowledge, and expertise needed by consumers to efficiently and rationally function in the marketplace. Consumers usually have a general knowledge of correct nutrition, but they scarcely use their knowledge in food decision-making and purchasing. Consequently, consumer knowledge of nutrition information and its use in food choices seems to be primarily influenced by individual features and personal conditions such as age, interest in healthy habits, and social status.

Role of Industrial and Regulatory Actors in Food Supply Chain

In food consumption, consumers trust various actors with responsibility for food production. This confidence can be regarded as a “taken-for-granted” attitude towards, for example, food buying (Grunert 2002). Confidence is based on familiarity (Siegrist et al. 2003). It is typically lost when a consumer’s expectations are disappointed (Kjærnes and Dulsrud 1998). Trust involves risk of disappointment and uncertainty and may evolve into confidence which requires specific knowledge and faith.

As food production is increasingly taken over by the food industry, trust might be placed in (1) regulatory authorities; (2) commercial organizations such as food producers, manufacturers, processors, retailers, and supermarkets; (3) local authorities and local chains of supply; (4) consumer movements; (5) food experts and gastro-nomic manuals; and (6) brands.

Need to Build Trust in Food: The Causes of Consumer Distrust in Food

The need to build trust in food may result from various situations that are encountered in the food

market. Food fraud events, the introduction of new production technologies, or new food additives are particularly important.

Food Fraud

Food scares concern about the safety and quality of food. Food fraud is a dishonest act or omission, relating to the production or supply of food that aims to increase personal gain which causes the damage or loss to another party. In recent years, there were a series of food scandals. One of the leading causes is the globalization of the food system that makes it harder for government agencies to live up to consumer demands for safe foods or to alleviate public concerns about food risks. Food industry fraud significantly reduced consumer confidence in the food supply chain. The scandals have also significantly contributed to the deterioration of the overall image of the agri-food sector.

For example, in Europe, in the 1980s there were concerns regarding the use of growth-promoting hormones in beef production, dioxins found in soft drinks, listeria outbreaks in France in 1999 and 2000, and foot and mouth disease starting in the United Kingdom. The most infamous of these was the Bovine Spongiform Encephalitis (BSE or mad cow disease) outbreak that started in the United Kingdom in 1986 and spread to other parts of Europe. In 2012, the “salt scandal” in Poland involved companies that sold chemical salt as a food salt. Another event is the 2012 counterfeit dried egg scandal: the common baking ingredient turned out to be dried fish with calcium and curcuma and only traces of egg.

New Technological Systems

Trust is crucial if consumers are to recognize and accept the benefits of new food technologies and feel assured that food regulation is protecting their best interests. However, new technological developments in the food supply may damage trust, especially when the safety of new products is questioned, as in the case where trials of genetically modified (GMO) peas were halted after an adverse immune response was detected in test animals. “Gene technology” has been portrayed as confronting the consumer with “alien” foods.

In Europe, many consumers believe that technology that interferes with the laws of nature is something hazardous. Genetic engineering requires specialized knowledge, which makes it difficult for consumers to understand what it is all about, how safe GMO products are, and how they will affect human health, leading to negative perceptions toward GMO foods. Bildtgård (2008) argues that the government can have a mediating role. However, we can see the states' authority as the universal arbitrator is being challenged by some sides. In modern societies, nongovernmental organizations increasingly articulate the consumer concerns about food. Those organizations, such as certification schemes, do not necessarily perceive the state as the legitimate actor for political authority.

Food Additives

The concerns regarding food production and safety may reflect consumers' lack of knowledge about the production and technology of food. Some studies have found that many consumers keep incorrect beliefs regarding food additives (e.g., the harms of artificial coloring) leading to concerns that may be not scientifically confirmed. However, scientific facts – especially when conveyed poorly or by vested interests – do not always pacify consumer worries, and often the legitimacy of the messenger is as necessary as that of the message. In recent years, increasingly intensive use of the food additives by enterprises has been noticed. The essential criterion for the selection of additives in the food industry should be the result of determining whether: (1) there is a technological need to use them; (2) the proposed substances and their additive content do not pose a threat to consumer health; and (3) the use of an additive to foods does not mislead the consumer as to the health quality of the food.

Risk Management Tools and Building Trust in Food

People also tend to trust institutions and information sources which are perceived to be open (Poortinga and Pidgeon 2003). Openness is

related to integrity and will translate into transparency, traceability of food producers, and the use of proper labeling.

Transparency

Transparency is the extent to which an institution assesses, controls, and conveys information about risk honestly and truthfully. Providing information regarding food production to consumers is the most crucial factor in building up trust. It must be noted that trust can be destroyed when the information provided is perceived to be exaggerated, biased, or not factual. Consumers are dependent on farmers and food processors they have difficulty assessing the ability and the desire of farmers and processors to combat food hazards, due to their lack of direct contact with them. However, consumers never have full access to knowledge of food production because information asymmetry exists between buyers and sellers. This asymmetry is considered to be the consumers' perceived risk (Bauer 1967). There are expectations that the producers should take the initiative to provide more information to increase transparency of their activities, that is, to provide consumer guarantees for food safety, freshness, and nutrition.

Transparency is reached when everyone always can see and understand the status of an operation. Transparency may concern various issues such as transparency of supply, value, cost, the openness of net chain, history, operation, strategy transparency, price and cost transparency, and market and product transparency. It should be noted that level of consumer and customer expectations for transparency is not static. There are changes along with better access to various sources of information as well the different claims on benefits are getting more fully accepted and higher appreciated by the public. Also, due to the length of the supply chain in food production, it is not enough to maintain a prominent level of transparency by a single producer, but especially crucial in the agri-food sector is the transparency of all entities in the supply chain. This can be demonstrated by application of food quality and safety standards and supply chain governance mechanisms, for example, organizational arrangements

between supply chain actors for information flow and exchange.

Traceability

Traceability may be defined as the ability to identify (at all stages of production and processing) foodstuffs or feeding stuff, animal-derived agents, or other substances intended for food production. In other words, this is the ability to locate an animal, commodity, food product, or ingredient and follow its history in the supply chain forward (from source to consumer) or backward (from consumer to source). Traceability has been identified as a preventative strategy in food quality and safety management, particularly when hazards or food scares occur, in which case a suitable traceability system will facilitate timely product recall and determination of liability. Traceability should prohibit missing information in the food chain and keep the product from losing its identity. It also benefits companies, for example, in the event of a crisis to identify the source of danger in the shortest time.

In general, traceability helps to build trust, peace of mind, and confidence in the food system. The food traceability system can also provide detailed information on food production, processing, transfer, and distribution, such as the birthplace of animals, feeding, medication, date of sale, slaughtering information, and other supply chain-related information. For other food system players, traceability is part of an overall cost-effective quality management system that can also assist in continuous improvement and minimization of the impact of safety hazards, by rapidly determining and isolating its sources. Furthermore, it facilitates prompt and efficient recall of products.

Traceability is a mandatory requirement for the agri-food sector in many countries (Gandino et al. 2009; Nambiar 2010). In the European Commission Regulation No 178/2002, food traceability is a detailed procedure. Food sector business should allow the precise identification of the origin of each food product through all the production and distribution stages. Moreover, various institutions and governments monitor multiple parts of the process or enforce industry-wide standards

concerning food quality control. For example, the ISO 9000 standard includes determining the scope of identification of product origin and later the selection of links in the supply chain while standards and codes help achieve progress.

Regarding the traceability issue, it is worth underlining the trend of shortening the food supply chains. This distance should also include the distance between the areas of production of other elements used in agriculture (e.g., fodder or pesticides of conventional output). As food chains have become longer and are based in multiple territories, producers and consumers are less likely to meet, which means that trust in food is less based on interpersonal relationships. This issue is related to importance to social closeness, which assumes that economic interactions are immersed in social relations. They allow the use of coordination mechanisms and information flow resulting from social embeddedness (Uzzi 1997). Short supply chains can eliminate some of the traceability issues found in longer chains.

Brand and Label Information

Labeling gives the ability for consumers to judge the trustworthiness of the food system actors. The qualities of the certified products are detailed on the product label, or through other information, such as brochures and Internet. These labels may inform consumers about the ethical aspects of the production process just as much as the nutritional and energy value of the product. In a time when increasingly responsibility for food choices is placed on the consumer, food labels constitute a source of information the consumer can use to gauge the relative risk and trustworthiness of the food item. There is the significant importance of a visible authoritative presence in the food system to strengthen trust and provide reassurance to consumers.

Food labels are informative, particularly about a new product, or if the consumer has never tried it before; has food allergies or intolerances in the family; and to help choose food related to some illness and diet, for example, type II diabetes, high cholesterol, heart conditions. Labels also provide freshness information about the use-by or best-before date; they help to identify product variants

(e.g., flavors of yoghurts, variety of orange juice – smooth or with bits); identify the country of origin (e.g., for traceability or fair trade); determine instructions for use; and determine if the product is organic, free range, vegetarians, or vegans, as well as suitable for religious practitioners (for example, Kosher or Halal).

The labels on the packaging of products may also indicate whether the product has been covered by a certification system. Many food-certification schemes are initiated by non-governmental organizations (run by, e.g., environmentalists, animal rights activists, social activists, or traditionalists) that oppose the current construction of the global food system and are working to create an alternative system that is, for example, environmentally sustainable and socially just. These actors use food labels to channel individual consumer choices for collective action by particular political agendas. Thus, it can be argued that food labels foster trust in food by promoting certain community-based norms and values in food production.

Unfortunately, the market is full of illegally labeled foods touting disease prevention or making claims such as “low fat” while having a high sodium content. “Gluten-free” applications are ubiquitous, without the backing of third-party certification such as some gluten-free certification program. Food originating from countries with a weak food safety record or questionable practices is a growing concern among consumers. For example, decreasing the package contents may be related to maintaining an illusion of the original size of the product. Moreover, many consumers while judging the safety and quality of processed food products use the brand as a reference to define trust in safety and quality.

Conclusion

Trust is related to voluntarily accepted duty and risk of consumption of food. The majority of consumers, however, rely on expert systems, regulators, and the food industry to provide them with information and to minimize the impacts of risky food consumption. Thus,

aspects of communication behavior, especially accuracy, adequacy, and credibility of information exchanged between the food system entities, are crucial to the development of trust in food. It helps to avoid potential losses of trust. Companies increasingly cooperate with competitors in the same industry to set standard values, spread risks, and shape opinions. Activities are driven by concerns about food safety help to establish even voluntary standards with an extensive list of competing norms, which progressively included a broader set of environmental and social concerns. Also, levels of consumer trust in food are influenced by the accuracy and degree or amount of open, honest, and transparent information exchange that takes place in those relationships.

Introduction

Urban agriculture is defined as the production of food and nonfood items through cultivation of plants, tree crop, aquaculture, and animal husbandry within urban and peri-urban areas. It also involves the processing and distribution of a diversity of foods and nonfood products, using large amounts of human and material resources, products, and services found in and around those areas. City dwellers in developing countries commonly use urban agriculture as a livelihood strategy to generate food and income, while those in developed countries may engage in gardening more for recreation. However, these goals are not mutually exclusive, and people engage in urban agriculture for a wide variety of reasons. No current and reliable estimates of the number of people participating in urban agriculture exist; however, Smit et al. (1996) roughly estimated the number to be about 800 million. Of these urban farmers, 200 million produce for markets and employ 150 million people.

The history of urban agriculture is the history of both cities and agriculture, which are intimately and intricately tied together. While there is disagreement about whether planned permanent settlements or agriculture came first, the two are mutually co-supportive and interdependent. So urban agriculture has existed throughout the history of cities, towns, and all permanent settlements. Indeed, agriculture is a fundamental component, along with permanent settlements, of civilization. The earliest documented form of urban agriculture is found in Shanghai, China, where productive lands continue to be used for urban gardening to this day (Girardet 2005). Urban residents have also cultivated home gardens for thousands of years. During the Middle Ages, kitchen gardens planted in large estates throughout Europe provided vegetables, fruits, cut flowers, and medicinal herbs to families and their servants (O'Brien and De La Escosura 1992). In other areas of the world, entire cities have been constructed to support urban agriculture. For example, Machu Picchu in Peru was built in the sixteenth century with infrastructure such as terraces and irrigation canals, as well as

systems for waste management and food storage (Lovell 2010).

Worldwide, urban agriculture continues to evolve to meet the needs of city residents. Increasingly, urban agriculture is seen as a response to rising food prices, urbanization, and the need to improve the livelihoods of the urban poor. In 2008, the world's urban population outnumbered its rural population for the first time, and by 2030, it is estimated that more than half the world's urban population will live in cities. In most developing countries, more than half the urban population lives below the poverty level of USD 1 per day. To cope with urban poverty, many people turn to farming; as much as 20% of food throughout the world is produced in urban and peri-urban areas. Studies in nine African cities reveal that on average, 35% of households engage in some form of agriculture, and by 2020, 35–40 million urban residents of Africa will depend on urban agriculture to feed themselves (Prain et al. 2010; Denninger et al. 1998). In China, where the 14 largest cities produce 85% or more of their vegetables with urban agriculture, the urban poor earn money by selling surplus produce from their gardens. Similar trends are found throughout South America, such as in Brazil, where more than 45% of the population is involved in urban agriculture. In many cases, urban vegetable production is more profitable than other available urban jobs.

Urban agriculture in developed countries is increasingly recognized as a valuable urban activity, and many cities are now incorporating urban agriculture into city planning and policies. Montreal, for example, has worked to protect its 95 community gardens and 75 collective gardens from the pressures of urban real estate development, recognizing that these gardens are important for urban food security, the environment, and as a way of bringing diverse communities together. Numerous other cities throughout North America and Europe have adopted similar policies to promote urban gardening. Additionally, urban agriculture has become more prevalent in many developed countries as interest has grown in agricultural sustainability. Urban gardening is now seen as a means of reconnecting people with

their food systems. In the Netherlands, programs such as *Gezonde Gronden* (Healthy Soil) have been introduced to educate city dwellers about specific methods of sustainable food production with the goal of enabling residents to grow food in their own town or region. Similar programs are now found in many major cities in North America and Europe.

Throughout history, communities around the world have created urban agricultural systems that are adapted to the local climate, cultural preferences for crops, and that utilize locally available technologies (Lovell 2010). Urban agricultural systems take many forms, including backyard gardens and farms on vacant public and semipublic land, such as those gardens found under power lines and along road reserves in many developing countries. Other gardens may be found on the grounds of schools, prisons, and other institutions or in densely populated settlements where residents maximize their space by farming in containers such as sacks or old tires or gardening on rooftops. Community gardens have been established in cities worldwide, and the intentional transformation of vacant public lands into community farms is also occurring. Whether as a response to urbanization and economic insecurity or as a means of reconnecting city dwellers with their food systems, urban agriculture has continued to grow and is now valued by many cities as a tool to deal with food insecurity and to manage the urban environment.

There are several important ethical issues arising from or affected by urban agriculture, including livelihood strategies and issues of food security, environmental management practices, climate change, the use and regulation of natural resources, and social and gender issues. This entry examines these issues.

Urban Agriculture for Livelihoods and Food Security

Confronted with poverty, unemployment, and food insecurity, millions of families in developing world cities and towns improve their access to food and raise income through agricultural

activities in urban and peri-urban areas. This is now widely accepted as an urban livelihood strategy. Urban agriculture provides benefits to the economy in terms of employment and income, particularly for women and other disadvantaged groups among the poor. Growing food in cities has some advantages over rural farming, including proximity to markets, low transportation costs, and reduction in postharvest losses because of reduced time between harvest and selling. While food insecurity historically was viewed as a result of inadequate agricultural production and food supply at the regional or national level, Sen (1981) showed that a household's food security status depends on its ability to access food by producing or purchasing it with its own assets. Urban agriculture can be an important part of an urban food security strategy either by providing additional income sources, increasing dietary diversity, or helping protect against seasonal unavailability in the food supply. Surveys conducted in the late 1990s in 24 cities, mainly in Africa and Asia, showed that people in poor households practicing urban agriculture ate more meals and had more balanced diets than other people. Data from Kampala, Uganda, in the 1990s suggest that children in urban farming households were better nourished than those in nonfarming households (Maxwell et al. 1998).

In times of conflict or other unrest, urban agriculture often keeps people fed when food supplies from the countryside are affected. Following the collapse of the socialist bloc in 1989, an economic crisis in Cuba created severe food insecurity throughout the country. As a result, thousands of urban residents began to cultivate urban gardens to provide food for their families. The government provided technical support and training to residents and relaxed laws on the sale of produce in urban areas. Although prior to the economic crisis urban agriculture was considered to be a sign of poverty and underdevelopment, it was quickly acknowledged as a key component of Cuba's national food security strategy (Altieri et al. 1998).

In North America and Europe, urban agriculture has also been used as a means of combating food insecurity. During the World Wars, upwards

of 20 million households in England and the United States planted victory gardens to supplement their food supply during times of food scarcity. In the United States, beginning in the 1970s, the federal government and local city councils began promoting urban community gardens as a way of revitalizing cities and providing food security to city residents who lived in areas with limited access to fresh produce. Much of the interest in urban gardening today centers around making fresh produce available to city dwellers at affordable prices. In the city of Detroit, numerous organizations are working with local citizens to convert vacant plots of land into community gardens and urban farms. Large areas of Detroit are considered to be food deserts, areas with limited access to food, particularly fresh produce. Many of the residents live at or near the official poverty level, so urban agriculture is a way of improving household food security and household nutrition. Other organizations, such as Growing Power in Milwaukee, have worked widely with households and youth groups to promote innovative urban farming methods as a way of providing both food and jobs to urban populations in Milwaukee and Chicago that live within food deserts in these cities.

Role of Urban Agriculture in Environmental Management

In addition to contributing to livelihoods and food security, urban agriculture can also play an important role in the sustainable development of urban environments. Waste management is a major challenge faced by urban areas worldwide. Rapid population growth accompanied by widespread poverty, sociocultural change, and weak, resource-poor local governments has led to inadequate waste disposal systems in developing cities. While governments grapple unsuccessfully with solid and liquid waste management, the urban poor are known to be involved in waste recycling and compost production on a limited scale in many towns. A study of urban food production in Kenya identified the widespread use of organic inputs by urban crop farmers (Lee-Smith

and Lamba 1991). About 70% of the city's solid waste is biodegradable material which, if recovered, could be used either as livestock feed or for compost making. Waste composition affects the amount and quality of compost that can be produced, and the higher the organic fraction, the better. In Mexico City, a barter market has recently been established where residents of the city can exchange recyclable waste, such as glass and plastic bottles, for tokens that are redeemable for fresh produce grown. This innovative program keeps waste out of local landfills and provides important income to urban farmers.

Wastewater farming is another important way in which urban farmers help recycle urban waste. In recent years, wastewater has gained importance in water-scarce regions like the Middle East and North Africa. Recycling of wastewater for irrigation in urban areas is a long tradition in many countries. In China, Egypt, India, Lebanon, Mexico, Morocco, Peru, and Vietnam, wastewater has been a source of crop nutrients for many decades. Jordan is one of the 10 most water-scarce countries in the world. A 2001 census of Amman found that 40% of the population used gray water to some extent to irrigate their gardens.

Urban agriculture may also benefit local environments by ameliorating the environment and improving the biodiversity in cities. Urban agriculture, in the form of agroforestry, often provides shade for people and livestock and supplies fruits and nuts. Trees also act as windbreaks and improve air and water quality, provide places for outdoor leisure, and conserve biodiversity. In some regions of the world, year-round production strategies in urban areas create a steady supply of seeds, which may be shared with rural relatives during the dry season. In many developed countries, the urban environment may actually be more diverse than rural farmland. In Germany and the United Kingdom, urban beehives actually produce more honey than their rural counterparts because the cities contain more trees and flowers than the intensively farmed rural areas (Deelstra and Giradet 2000). City gardens may also improve biodiversity of plants, as well as attracting beneficial soil microorganisms, insects, birds, and other animals.

While farming in cities is beneficial in many ways for urban environments, it is not without hazards. Urban agriculture activities may contaminate local water sources if overly high inputs of fertilizers and pesticides are used. Neighbors may complain of dust, odors, and noise created by the urban farms. If urban farmers do not manage their farm wastes well, these may clog the storm drains and pile up in the streets, leading to bad sanitary situations. Organic solid wastes that are used in compost production may transmit pathogens or attract disease vectors. Additionally, contamination of soil and irrigation water with heavy metals also poses health risks to many farmers or consumers of food grown in urban areas. Heavy metal consumption can result in long-term diseases, including cancer, neurological disorders, and chronic pain. Unlike most biological pathogens, which result in immediate illness, it can take years for health problems to manifest due to exposure to heavy metals. It is becoming more common in developed countries for urban garden projects to encourage testing of soil for heavy metals. However, this remains an expensive endeavor and is virtually nonexistent for urban agriculture in developing countries.

Urban Agriculture in the Context of Climate Change

Predicted changes in climate, including more intense droughts, flooding, increased frequency of extreme weather events, and higher temperatures within urban heat islands, will require adaptations within urban areas. Thus, urban agriculture has the potential to make cities more resilient to future climatic change and to manage the risk imposed by more extreme weather events and natural disasters. Among city dwellers, the urban poor are particularly vulnerable to the impacts of climate change. Widespread drought or flooding negatively impacts rural agriculture, driving up urban food prices. This is particularly problematic in developing countries where urban residents may spend up to seventy-five percent of their household income on food. Urban agriculture enhances the coping strategies of the urban poor,

providing them food and jobs in times of need and creating a social support network among urban farmers. Farming in the city increases urban green spaces, which improves water infiltration in low-lying areas, which reduces the impact of higher rainfall during extreme weather events. Urban farms planted on hill slopes provide groundcover and may also prevent landslides during heavy rains. Additionally, urban agriculture may provide shade in some areas of the city, reducing the effect of the urban heat island.

In addition to helping urban residents adapt to climate change, urban agriculture can play a positive role in reducing urban energy use and greenhouse gas emissions. Food grown in cities reduces the reliance of urban residents on food imported from rural areas. Urban agriculture produces food in close proximity to consumers, requiring less energy for transportation, storage, and packaging of the food. Urban agriculture often relies on recycled organic waste for fertilizer. By composting and using organic waste for agriculture, this reduces the need for fertilizer and reduces methane gas emissions from the decomposition of organic materials placed in landfills.

In many cases, the benefits of urban agriculture as a means of mitigating climate change are secondary to the main purpose of improving household food security. However, some cities are adopting policies that specifically target urban agriculture to reduce the impacts of climate change. For example, the city of Chicago has adopted policies to promote rooftop gardens. These green roofs insulate a building, reducing energy spent on heating and cooling. They also absorb water during rain events, preventing runoff and erosion into storm sewers. Additionally, green roofs help absorb heat reflected off of concrete, diminishing the urban heat island effect and reducing energy used on artificial cooling systems.

Conflict in Resource Use and Policy Issues Around Urban Agriculture

Acknowledging the many benefits of urban agriculture, it is now actively being incorporated into

urban planning in many areas of the world. Globally, cities have begun to adopt official zoning policies to facilitate the growth of urban agriculture. Specific policies vary widely, but generally, they aim to promote sustainable urban food systems by designating land for community gardens, providing technical support, and fostering economic opportunities for growers. However, despite its long history, the recent interest and explosion of urban agricultural activities have meant that official policy has not kept pace with the growth of urban agricultural activities, sometimes leading to conflicts between farmers, other residents, and city officials. There are various forms of conflict in resource use experienced by urban farmers. One form of conflict is due to different interests in the use of land, such as between urban farms and other types of urban development, including houses, industry, commercial properties, and roads. In many countries, urban farmers lack tenure for the land they farm, instead occupying vacant or unused lands such as open reserves near the side of roads. This places farmers in constant battles with local city authorities, who may harass farmers, vandalize their farms, or demand fines or bribes on a regular basis (Foeken 2006). Other conflicts between urban farmers and residents occur over the keeping of livestock. In North America, increased interest in raising chickens and other small livestock within city limits has forced many cities to rethink zoning laws. While some cities, including New York and Chicago, have opted to allow residents to raise a limited number of animals, opposition from other residents concerned about the noise and smell has kept other cities, like Montreal, from legalizing poultry keeping within city limits.

For many years, urban farming was not included in policy frameworks in cities and towns, but today it is being recognized for its contribution to poverty alleviation, food security, and sustainable urban development. In 2007, the American Planning Association adopted a policy that encourages its members to help build stronger, sustainable, and more reliant local food systems. In Argentina, policy support for urban agriculture appeared as a response to its 2001 economic crisis, while in July 2009, the mayor of San Francisco asked all municipal departments to

conduct an audit of land under their jurisdiction to create an inventory of land suitable for gardening as part of first-ever citywide food policy. A minister's conference on urban agriculture in East and Southern Africa, held in 2003, resulted into the Harare Declaration on urban and peri-urban agriculture, signed by all the participating nations. Kenya is currently developing a national policy on urban agriculture, while its national land policy has a section on urban agriculture and urban forestry. Kampala, the capital city of Uganda, has guidelines and a department of urban agriculture that institutionalizes the practice. Researchers, policy makers, and urban planners have accepted urban forestry management as one important strategy to improving urban living and working environment. In China, for example, research projects and education programs have been initiated to better plan for urban forests.

Social Capital and Gender in Urban Agriculture

Urban agriculture brings city dwellers together and helps generate social interaction. Self-help groups of young people, women, and vulnerable people including the elderly meet as a result of their involvement in urban agriculture, giving them an opportunity to organize and share information and skills and together address their problems. This helps improve well-being while providing a voice that otherwise would not be heard. Together, these groups are able to advocate for technical, financial, or policy issues with both government and non-governmental organizations. For instance, the Musikavanhu Urban Farmers movement in Harare, Zimbabwe, originally formed in Budiro and Glen View and has now spread to the other low-income suburbs. It started with seven families meeting and agreeing to form a group that would work together and engage in urban farming. Currently, the movement counts more than 5000 members of which over 90% are women.

Community garden projects around the world have been shown to foster relationships and create social capital among community members. A study of the Dig In community gardens in

Melbourne found that garden members created social support networks that people turned to in times of crisis and increased social cohesion among the garden members (Kingsley and Townsend 2006). The California Healthy Communities Project runs community gardens in 65 cities throughout California. They also found that these community gardens helped to build the capacity of their communities and were an excellent public demonstration of public health efforts designed to promote community engagement. In Philadelphia, a study of gardeners and non-gardeners found that people who gardened were more active in participating in other community projects. They were also likely to share the produce from their gardens with friends and family members (Blair et al. 1991).

In many cities, the majority of urban agricultural producers are women (on average around 65%). Urban farming is a viable alternative to wage labor for women who lack access to formal employment due to limited education and training or sociocultural factors limit in their freedom of movement (Hovorka et al. 2009). As a largely informal sector activity, urban agriculture is in many cases especially effective and efficient for married women with children or women heads-of-households because it is often performed close to the home and combines well with their household responsibilities. Urban agriculture can be undertaken with relatively little capital, technology, and inputs. It is thus attainable and affordable for women with limited education and resources and often stimulates the use of indigenous practices. Urban agriculture contributes to empowerment, improved self-esteem, leadership, capacity building, increased independence, and freedom of women. It is important to note that for women, urban agriculture is not an overload of activities but rather a place to build their personal development and their capacity for social interaction and organization and overcome many conditions devaluation, subordination, and exclusion.

Challenges facing women interested or participating in urban agriculture activities are numerous. For example, women face severe constraints in accessing, using, and/or controlling land in cities compared to their male counterparts. Men

tend to have the first choice of any available vacant land, leaving women with low quality or less secure plots of land often located at a considerable distance from home. Even within households with adequate land resources, wives may be constrained in their ability to access these plots given this inequitable access to urban land between themselves and their husbands. A related challenge to land tenure is the distance to agricultural plots whereby women are often left to travel extensive distances to marginal lands, requiring considerable time, physical effort, and financial costs for transportation, if available. Women also face constraints in terms of urban agriculture production itself. Women often lack inputs and working capital, as well as access to knowledge and information on the use of modern inputs and technologies. The latter is partly due to women's limited exposure to commercial urban agriculture or to limited access to training courses offered by institutions or nongovernmental organizations. As such, Alderman et al. (1996) estimated that reducing inequalities in human capital, physical capital, and current inputs between male and female farmers in sub-Saharan Africa could potentially increase agricultural productivity by 10–20%. For future agricultural research to produce meaningful changes, the needs, preferences, and constraints and differential roles of female farmers and women engaged in agricultural production must be recognized.

Summary

Urban agriculture refers to the production, processing, and distribution of food and nonfood items within urban and peri-urban areas. It is often practiced as a livelihood strategy to generate food and income for poor urban residents, but it is also a form of recreation that connects people to the source of their food. In addition to contributing to livelihoods and food security, urban agriculture has been shown to increase social capital and foster beneficial relationships among community members. It can also play an important role in the sustainable development of urban environment by aiding in the recycling of solid waste

and wastewater, and it may serve to reduce the carbon footprint of urban areas by reducing urban energy use and greenhouse gas emissions. As rural food systems are impacted by climate change, urban agriculture is becoming a coping strategy for the urban poor. Challenges to urban agriculture include inadequate access to land and insecure land tenure, exposure to environmental toxins when farms are located in previously degraded environments, conflicts between different land users, and a lack of policies in cities to help regulate urban agriculture.

Vegan Lifestyle

Alexander Christian
 Duesseldorf Center for Logic and Philosophy of
 Science, Heinrich Heine University Duesseldorf,
 Duesseldorf, Germany

Introduction

The term “veganism” denotes both a dietary practice and a moral position with regard to the relationship between human and non-human animals (see ► [Veganism](#)). Veganism as a *dietary practice*, which is implied by moral veganism, means to refrain from the consumption of animal products for dietary purposes. Dietary vegans exclude meat, fish, eggs, dairy products, and other animal-derived products from their diet and therefore take a stricter stance toward the use of animal products compared to vegetarians, who consume eggs or dairy products (see ► [Vegetarianism](#)). As a *moral position*, it has large implications for individual lifestyles and society’s stance toward non-human animals, insofar as moral veganism forbids all forms of exploitation of animals serving human ends, including especially their use in the production of food and clothing. Motivated by ethical, religious, ecological, or health concerns, most vegans strictly exclude animal products not only from their diet but also refrain from wearing clothes made from wool, silk, or leather, do not use cosmetic products containing fish scales, and avoid hygiene products like soap made from animal fat.

In this entry, the first two sections provide information about the prevalence of a vegan lifestyle in Western societies and the historical precursors of contemporary veganism in England and the United States. Section “[Arguments for Veganism](#)” briefly summarizes major arguments from moral philosophy, religion, ecology, and medicine in favor of dietary veganism. The following sections examine the dietary implications of a vegan lifestyle, some linguistic conventions among vegans, and veganism as a fashionable part of youth cultures in Western societies. The final section is concerned with discrimination against vegans and illustrates the occasionally emerging conflicts between vegan and non-vegan lifestyles.

Prevalence of Vegan Lifestyle in Western Societies

In Western societies, veganism is an increasingly popular lifestyle, whose adoption is correlated with sociodemographic characteristics like a higher education, female gender, young age, urban residence, and above-average income (Mensink et al. 2017). Estimated percentages of vegans in Western countries are 1.05% in the United Kingdom (Gallup 2016), 1% in Austria (Vegane Gesellschaft Österreich 2014), 1.6% in Germany (Skopos 2016), 1% in Italy (Eurispes 2016), 4% in Sweden (Demoskop 2014), 1.5% in Switzerland (DemoScope 2017), 0.27 in the Netherlands (Nederlandse Vereniging voor Veganisme 2014), and between 0.5% and 2% in the United States and Canada (Gallup 2016).

Although only a comparable small share of the population in Western societies enjoys a vegan lifestyle, the availability of vegan products, services, and information resources has grown significantly in the last decade. This development is largely driven by four factors, which are (i) activism by a nonreligious social movement rooted in nineteenth-century Britain and United States of America, (ii) an intensified cultural interchange between Western and non-Western societies with a higher share of vegetarians in their respective populations, and (iii) improved ways to communicate information relevant for a vegan

lifestyle, like knowledge about vegan substitutes for animal-based products and vegan recipes. Finally (iv) the insight that due to socio-demographic characteristics of vegans, like above-average income and urban residence, vegan consumers posit a lucrative market has led to the inclusion of vegan product lines in portfolios of producers of goods and services.

Origins of Contemporary Western Veganism

This entry is focused on veganism as a contemporary nonreligious social movement, which emerged from the movement of vegetarianism in the nineteenth century in the United States of America and the United Kingdom (see ► [Buddhism, Cooking, and Eating](#); ► [Christian Ethics and Vegetarianism](#); ► [Hinduism and Food](#)).

Early contemporary advocates of a plant-based diet, like Percy Bysshe Shelley (1792–1822) and Sylvester Graham (1794–1854), who also advocated abstinence from alcohol, were primarily motivated by health concerns. The first vegetarian societies were established in the United States by Amos Bronson Alcott (1799–1888) in 1834 (*Temple School*) and 1844 (*Fruitlands*). In England, the first vegetarian societies were founded by James Pierrepont Greaves (1777–1842) in 1838 (*Concordium*), whose members later founded the *British and Foreign Society for the Promotion of Humanity and Abstinence from Animal Food* in 1843 and the *British Vegetarian Society* in 1847.

The term “vegan” was coined by Donald Watson in 1944, after his request to devote a section of the *Vegetarian Messenger*, the bulletin of the *British Vegetarian Society*, to the topic of nondairy vegetarianism was turned down. Watson derived the term “vegan” not from the Latin word “vegetus” (Engl. vivid/strong/fresh, which is the linguistic root of “vegetarian”) but from the English word “vegetable.” Other proposed terms for the strict vegetarian position he had in mind were “allvega,” “net-vegetarian,” “dairy-man,” “vitan,” “benevore,” “sanivores,” and “beaumangeur” (Stepaniak and Messina 2000). In 1944 Watson founded the *Vegan Society*, a

secession from the *Vegetarian Society*, which from 1945 on published a quarterly newsletter first under the name *The Vegan News* (Watson 1944) – later renamed to *The Vegan* (Watson 1946). Since 1948 the front matter reads “Advocating living without exploitation” (Watson 1947, 2). The first vegan society in the United States was founded in 1948 by Catherine Nimmo (1887–1985) and Rubin Abramowitz. In 1960 Hom Jay Dinshah (1933–2000) founded the *American Vegan Society*. Common in these societies was the view that a vegan lifestyle is first and foremost a consequence of the rejection of animal exploitation due to moral reasons. (For a more comprehensive overview on the history of veganism in Western societies, see Taylor and Twine (2014), part IV, and Castricano and Simonsen (2016).)

Arguments for Veganism

Veganism is a profound lifestyle choice, which goes beyond a mere dietary restriction, and is most often motivated by a moral belief system, either made explicit or based on moral intuitions and moral feelings like sympathy for suffering animals. Arguments in favor of veganism might include one or a combination of moral arguments, health-based arguments, and ecological arguments (e.g. Mancilla 2016). It can also be motivated by individual judgments of taste.

Moral arguments for vegetarianism and veganism were developed within specific ethical frameworks, like consequence-based theory, in particular utilitarianism (Singer 1975), rights-based theory (Regan 1983), obligation-based theory like Kantianism (Korsgaard 2014), community-based theory like contractualism (Rowlands 1997), relation-based theory like feminist ethics (Adams and Donovan 1999), and virtue-based theory (Hursthouse 2000). Also, in political theory, some scholars explore the relationship between human and non-human animals in a political context (Donaldson and Kymlicka 2011) (see ► [Veganism](#), for a detailed discussion of moral arguments).

A common assumption among proponents of veganism is that human interests in the

consumption of animal products or economic interests involved with their production generally do not outweigh the interests of non-human animals in not being harmed, deprived of certain goods, and killed. The basic idea behind this practical conclusion is that non-human animals are sentient beings, who have the capacity to experience pleasure and pain, and that this is what makes them morally considerable. Moral vegans consider the use of non-human animals for the production of food or clothing, or for drug testing, etc. as exploitative, since it most often – if not always – results in unnecessary suffering of non-human individuals.

Philosophical frameworks differ in their treatment of other criteria for moral consideration (besides sentience), the attribution of moral or legal rights to non-human individuals, and other philosophical issues with regard to the adequate moral consideration of non-human animals. In the context of vegan lifestyle, these particular issues are less important than the two strategic approaches to veganism, which are concerned with solutions to the exploitative nature of the relationship between human and non-human animals: Whereas welfarist approaches to veganism seek to improve living conditions of animals in human societies, abolitionists seek to abandon the use of animal products and forced services of non-human animals. Among animal rights advocates and political activists, this distinction is important, since abolitionists might conceive welfarist attempts to improve living conditions as ill-founded attempts to sustain the status quo of animal exploitation, whereas proponents of animal welfarism might interpret abolitionists attempts to ban the use of non-human animals altogether as an unattainable ideal (cf. Francione and Garner 2010). This distinction also sheds some light on individual lifestyle decisions and consumptive behavior of vegans, since vegans with a welfarist mindset might consume products from sources, which ensure a relative degree of animal welfare deemed as acceptable. Abolitionists on the other hand, who insist on a strict congruence between the end of animal exploitation and practical implementation of this ideal, might deem deviance from a thorough veganism in all walks of life as inadequate.

A second arguably popular way to motivate a vegan diet is to point to detrimental health effects for consumers of an animal-based diet. Here, the avoidance of highly caloric animal products, residues of antibiotics, and hormones in animal flesh is a common argument to motivate a strict plant-based diet. Also, proponents of dietary veganism occasionally attribute the occurrence of particular diseases such as adiposity, hypertension, diabetes mellitus, allergies, and heart diseases to an unbalanced diet based on animal products. Whether a plant-based diet has a positive effect and, respectively, reduces the risk for those diseases is a controversial empirical question. Research about health effects of a vegan diet indicates that vegans have, compared to omnivores, a reduced risk for adiposity (Newby et al. 2005) and hypertension (Appleby et al. 2002). Yet medical literature also documents risks of malnutrition such as occasional deficiencies in calcium, iron, omega-3 fatty acids, vitamin D, and zinc and a common lack of iodine, creatine, and vitamin B12 due to a plant-based diet. Recommendations of health authorities differ: In Germany, the *Deutsche Gesellschaft für Ernährung* does explicitly not recommend a vegan diet for pregnant women, lactating women, infants, children, or adolescents (Richter et al. 2016, 92). Vegans should permanently take dietary supplements, in particular for vitamin B12, and pay special attention to an adequate intake of nutrients. Also vegans should seek advice from a nutrition counselor, and their supply of critical nutrients should be regularly checked by a physician (Richter et al. 2016, 92). The American Dietetic Association (ADA)'s official position is that an appropriately planned vegetarian diet, including vegan diets, can be considered healthy and nutritionally adequate and may provide health benefits in the prevention and treatment of certain diseases. A well-planned vegetarian diet is considered as "[...] appropriate for individuals during all stages of the life cycle, including pregnancy, lactation, infancy, childhood, and adolescence, and for athletes" (ADA 2012, 1277). Likewise to the aforementioned recommendations, the ADA also highlights the importance of professional dietary assistance and monitoring for malnutrition.

A third type of argument relates to environmental damages caused by an animal-based production of food. The production of animal-based products is generally considered a relatively inefficient transformation process, since animal products like meat or dairy products require a higher investment of resources in terms of water, soil, energy, fertilizer, and pesticides compared to plant-based alternatives (Marlow et al. 2009). In addition to this, the environmental impact of industrial animal agriculture has led to a reduction in biodiversity among wild animals, desertification, intrusion of invasive plant and animal species, and increased emissions of greenhouse gasses (Food and Agricultural Organization 2006).

In addition to the aforementioned types of arguments, there is also the possibility that individual judgments of taste motivate a decision for a vegan lifestyle. Another way of motivating dietary veganism without resorting directly to moral considerations and instead evoke the fitting preferences in potential vegans. A common strategy in vegan activism is, for example, to place a special emphasis on plant-based products and suggest vegan recipes, clothing labels, and vegan substitutes for animal-based products, without highlighting the assumed moral obligation to adopt a vegan lifestyle. It is also common that organizations in the animal rights movement, like *People for the Ethical Treatment of Animals* (PETA), advocate a vegan lifestyle and make recommendation for vegan clothing brands, substitutes for animal-based food, and vegan recipes on their website (<https://www.peta.org/shop/>, retrieved December 29, 2017).

In most secular Western countries, ethical reasons (broadly construed) and environmental considerations, alongside health concerns, are the decisive reasons to adopt a vegan lifestyle, whereas in Asian societies, like India, cultural or religious traditions play a greater role in adopting a vegetarian or vegan lifestyle. Also, since veganism is now established as a primarily countercultural food movement, the adoption of a vegan lifestyle and the identification with veganism are a means for identity formation and development in secondary and tertiary socialization.

Vegan Cuisine or What Do Vegans Eat After All?

As a countercultural food movement, veganism was popularized by cookbooks focusing on a vegetarian or vegan diet. Today's abundance of vegan cookbooks, which also cover the cuisine of countries with a traditionally high share of animal-based dishes like Japanese cuisine (c.f. Schinner 1999), have their roots in books like Rupert H. Wheldon's *No Animal Food: Two Essays and 100 Recipes* (1910) and Frances Moore Lappé's *Diet for a Small Planet* (1971), which were highly influential during their time. With regard to contemporary vegan cookbooks, six types of books can be distinguished: (1) books with recipes for staples; (2) books with recipes for specific culinary areas, like pastry, ice cream, baking, vegan cheese, or smoothies; (3) books with recipes from a specific national cuisine; (4) books covering health-focused vegan dishes; (5) books with recipes for a specific social setting, like vegan street food or barbecue; and finally, (6) books including vegan recipes, which are the individual creative work of a chef. Most of the books on the European, UK, and US market include a rationale for a vegan lifestyle that goes beyond pointing to a gustatory pleasure and includes health reasons, environmental reasons, and often simplified or emotionalized moral reasons for a vegan diet.

Since dietary vegans eat no animal-based products, finding alternatives for these products is crucial. Three groups of products are especially important; these are substitutes for dairy products, meat, and eggs. Dietary vegans can substitute dairy products, with substitutes made from rice, almonds, soy, and hemp. Meat can be substituted with products like seitan (based on wheat gluten), tofu or tempeh (based on soy beans and soy curd), mushrooms, jackfruit, eggplant, and various other legumes (like lentils, chickpeas, and beans). Also, some vegans prepare vegetables like meat-based dishes. For instance, celery and oyster mushrooms can be prepared like schnitzel, and nuts can be used as a basis for meatloaves. Both with regard to meat substitutes and milk substitutes, one common problem is that certain restrictions with regard to the naming of vegan alternatives hold

by law, which hamper the identification of the substitutive nature of a vegan product. For instance, under European law, soy milk or vegan butter is forbidden to be labeled as “milk” and “butter”; the same holds true for products which are traditionally produced with animal parts like sausage or meat products. Such legislation makes it harder to identify a vegan product as a substitute for an animal-based product. Due to such regulations, producers of vegan substitutes often add references to the substituted product, i.e., they add “like ham” or “mozzarella style.” Substitutes for egg are varied, yet, due to differences in heat stability and function as an organic binder, egg substitutes have to be chosen in view of the dish that one wants to prepare. Vegan substitutes for eggs include flaxseed, silken tofu, cornstarch, baking soda and vinegar, ripe bananas, soy flour, chia seeds, applesauce, and arrowroot powder.

Besides a moral motivation for a vegan lifestyle, also the self-experience and hobbyist nature of a vegan lifestyle – in particular finding vegan substitutes for animal-based products – is a driving factor for vegans. Yet, due to lack of time or interest in culinary intricacies, the transition from an animal-based diet to a plant-based diet might be complicated for most people. A vegan lifestyle seems to be adopted primarily by people in those demographic groups which yield favorable conditions for solving problems that come with basic changes in one’s diet: young, well-educated, and with free time on their hand. Almost all vegans look for vegan versions of classical dishes and recipes, be it vegan scallops made from oyster mushrooms or something ordinary like vegan gyros made from thinly sliced smoked tofu.

Linguistic Conventions

Among vegans, in particular those engaged in theoretical discourse about moral veganism, some linguistic conventions seem to hold, which are intended to lay open the exploitative nature of the relationship between human and non-human animals. For instance, vegans show some tendency to avoid words which obscure animal suffering, subjectivity of animals, animal

exploitation, and oppressive mistreatment, like “meat” (instead of “animal parts” or “flesh”), “pet” (instead of “companion animal”), “veal” (instead of “flesh of calves”), “sacrifice of an animal” (instead of “killing a non-human subject”), and the like. Also vegans who adopted linguistic conventions of moral veganism typically deny a factual and linguistic dichotomy between “humans and animals”; instead they contrast “humans” with “non-human animals.” It is also common to avoid the grammatical neuter (it, which, etc.) for unnamed non-human animals and instead only use the gendered pronoun (he, she, him, her, who, etc.) in order to emphasize the individuality of non-humans. This is sometimes also achieved by adding “subject” or “individual.”

To which extent these linguistic conventions are a part of individual linguistic practice is a matter of degree among vegans, yet in some scientific linguistic communities within the humanities, these conventions are well-established. For instance in *Critical Animal Studies* and *Human Animal Studies*, it is more and more common to make animal agency and subjectivity of non-human animals explicit. Here it might be thought more adequate to write “A dog walks with his human” instead of “A man walks his dog,” in order to express shared mutual agency between a human and a non-human subject doing something together (go for a walk).

Veganism in Youth Cultures

Veganism as a lifestyle choice is common among people who identify themselves as proponents of animal rights and animal protection, environmental activists, and members of certain religious groups (Jewish vegetarianism, Christian vegetarianism, and Rastafarianism). Yet veganism has a special standing in some youth cultures (Schwartz 2005, 117–123), insofar as it gives juveniles the opportunity to differentiate themselves from others and form a distinguishable personality and a way to express opposition to default values held by older people as well as differentiate themselves from peers in the same or in near social cohorts. This is something that is important in

character development, in particular in liberal societies, which value individuality over conformity in context of matters of taste and ways of life.

Two examples might illustrate this point: In the straight-edge scene, a group within the hardcore punk movement, veganism is seen as one of the three principles, besides abstinence from drugs and spontaneous sexual intercourse. Besides being a part of straight-edge ideology, which is traditionally left-wing oriented, also among proponents of far right political ideologies have adopted and openly proclaimed veganism and animal rights – to the great displeasure of proponents of animal rights. Whether activism in Internet forums and on video streaming platforms, in which in particular young proponents of alt-right movements advocate a vegan lifestyle, is authentic or just preys on a young reader – respectively, viewership – can be debated. Historically, it is doubtful that animal rights are a genuine ideological part of national socialism and the modern alt-right movement (Heubach 2013). Vegetarianism and veganism rather seem to be used occasionally to address young peer groups and discredit religious groups, in particular Jews and Muslims with food norms concerning the legitimate consumption of animals.

Discrimination Against Vegans

Oscar Horta highlights that a morally motivated vegan lifestyle is in stark opposition to mainstream lifestyles which allow for the consumption of animal-based products, a fact that can in turn lead to discrimination against vegans (Horta 2017). The vegan opposition to cultural practices that are deemed by vegans as immoral is met with irritation and incomprehension to the brink of discrimination. Since vegans are far outnumbered – they make up approximately 1% of the population in Western societies – the direct and structural discrimination of vegans is far more common than the discrimination of vegans against people with a meat-based diet. It can take various forms, like harassment, problems at work, or a lack of vegan food at private gatherings, public

events, and restaurants. Besides minor inconvenience to find adequate food or substitutes for animal-based products, the more serious problem is of structural nature: Vegans are often forced to contribute to, or to participate in, acts which result in animal exploitation against their will, and resistance against animal exploitation would result in crimes. One example for this is government aid for producers of animal-based products financed by taxes. Here a morally motivated vegan is practically forced to participate in acts of indirect animal exploitation. People who have adopted a vegan lifestyle might perceive this as a kind of discrimination.

Since morally motivated vegans conceive their lifestyle choices as a result of their opposition to the discrimination of humans against non-human individuals, Horta characterizes this type of discrimination against vegans as a form of second-order discrimination. The discrimination against vegans is a discrimination against those who oppose another (first-order) form of discrimination (Horta 2017). It is similar to the discrimination against feminists, which might show in derogatory talk about “bra burners” or “women’s libbers” by sexists. Like sexists whose discrimination against feminists implies the rejection of feminist ideals, discrimination against vegans denies the moral legitimacy of vegan ideals.

Summary

This entry discussed various aspects of a vegan lifestyle, while the focus lied on veganism as a dietary practice. Veganism is a comparably rare lifestyle in Western societies, and it is associated with sociodemographic characteristics like a higher education, female gender, white ethnicity, young age, urban residence, and above-average income. Emerging from vegetarianism movements in nineteenth-century Britain and United States, veganism in Western societies is often motivated by moral arguments, health reasons, environmental considerations, and individual judgments of taste with regard to the consumption of animal-based products. This is a distinguishing feature of a Western vegan lifestyle, compared to a

more often religiously motivated veganism in Eastern societies. This entry highlighted some practicalities of dietary veganism by giving examples for vegan substitutes for animal-based products and identified problems in identifying vegan alternatives and adopting a vegan diet. After indicating some linguistic convention, which can be found among vegans, and a short note on veganism in youth cultures, it called attention to individual and structural discrimination against vegans in non-vegan societies. Although dietary veganism is at the heart of a vegan lifestyle, this entry left out the part of a vegan lifestyle, which goes beyond the avoidance and substitution of animal-based products in the context of nutrition.

Veganic Farming

Synonyms

Green manure; Organic; Stockfree; Vegan

Introduction

Veganic (vegan-organic) is a form of gardening that avoids the use of toxic sprays and chemicals as well as fertilizers that include animal remains

and animal manure. While organic gardening avoids synthetic chemicals, numerous organic fertilizers contain blood, bone, offal, hooves, horns, fish remains, and feathers. Veganic farming avoids these products because many of them derive from slaughterhouses and industrial farming and are processed into blood meal, bone meal, and fish emulsions. Cultivating without digging to not disturb the soil organisms in the top inches of the soil is an important feature of veganic farming. Farmers, instead, use mulching techniques.

Most veganic farmers are motivated by vegan principles and lifestyle practices and refrain from using products derived from animals and from raising animals as livestock.

Some of the non-animal products and techniques used in veganic gardening including hay mulches, green manure, seaweed, Epsom salts, and rock potash. Veganic farming is believed to produce plants that are healthier for consumption since the fertilizers, contrary to animal manures, do not contain antibiotic residues or parasitic diseases such as E.coli 0157:H7. Animal rights activists support veganic agriculture, because the methods do not depend on the exploitation of animals.

Brief History

It is believed that veganic techniques have been utilized for centuries in Chinese, Greek, and Roman agricultures. Rosa Dalziel O'Brien and her son Kenneth appear to be the most well-known and widely cited veganic horticulturists. The Dalziel O'Briens began farming without the use of animal waste products in the 1940s, but the word veganic did not appear in publication until 1986. The *Vegan* (magazine of The Vegan Society) published an article by Rosa Dalziel O'Brien and Kenneth Dalziel O'Brien published a description of the techniques in *Veganic Gardening, the Alternative System for Healthier Crops* (1986a). In the 1940s, Geoffrey L. Rudd amalgamated the words vegetable and organic to differentiate between organic gardening with and without manures (Stepaniak 2000). Kyle Kushman began to popularize the term and the techniques in 2009 for cultivating marijuana.

A Selection of Techniques

Veganic gardening maintains soil fertility using plant-based methods. The Dalziel O'Brien family built on compost techniques developed by Maye E. Bruce (Bruce 1945; Dalziel O'Brien 1986b). The initial O'Brien compost method, described as "intensive gardening" by Rosa Dalziel O'Brien (1956) included charcoaled wood on the soil base, then layers of old straw, green waste, and lime to improve soil fertility. While composting is a basic element of veganic farming, other processes include: green manuring, mulching, crop rotation, and natural insect control. Veganic farmers also encourage the natural activities of wildlife, because animals such as frogs and hedgehogs will feast on leaf-eating slugs and snails.

Composting

Composting is a key ingredient to veganic gardening. British botanist and Indian governor Sir Albert Howard (1873–1947) assisted in the creation of the "Indore method" which consisted of layering freshly cut vegetation with dead leaves and vegetation to create an organic mix of compost for plant food (Linzey 2014). Both Bruce and the Dalziel O'Brien family utilized composting in their methods. Modern veganic farmers continue to compost; however, the methods have changed over the years. Some of the organic matter used in veganic gardening includes: grass cuttings, old hay, tree leaves, spent hops, comfrey, garden waste, (non-animal) organic material from kitchens, washed-up seaweed, and chipped branch wood (Vegan Organic Network 2016).

Green Manuring

Small farmers in Ghana refer to chemical fertilizers as "the devil's salt" (Madeley 2002). In addition to avoiding the use of animal products in veganic gardening, the elimination of chemical fertilizers and animal by-products also helps evade an abundance of saline and acidity. Veganic farmers use green manure on their plots which improves soil productivity. This ancient farming method was employed by Chinese thousands of years ago (Pieters 1927). To create green manure, farmers grow crops that will be worked into the soil later.

Green manure adds organic residues, conserves and recycles plant nutrients, protects the soil from erosion, and reduces the amount of nitrogen fertilizer required. Some plants that are used for green manuring include: blank lentil, field pea, and sweet clover (Alberta Agriculture and Forestry 1993). Because these plants lie low to the ground, they add nitrogen to the soil and suppress weeds.

Human and Environmental Health

It is argued that the elimination of dependence on domesticated animals can improve human health and the health of the planet. The Food and Agriculture Organization of the United Nations (FAO) (2006) claims that livestock extensively contribute to climate change and the deterioration of the world's water, land, and biodiversity resources. It is suggested that over the years, livestock farming has assisted with deforestation and pollution (Janzen 2011; Madeley 2002). The use of manure has become questionable because of fear of *E. coli*, staphylococci, and enterococci bacteria contaminating crops. The *E. coli* epidemic in Walkerton, Ontario, Canada, is an example of factory farms causing ecological and social repercussions. Seven people died from drinking water that was contaminated by manure directly linked to factory farms and more than 2300 people became ill (Ali 2004). Livestock farming can be ecologically and socially damaging, but Janzen (2011) suggests that small amounts of manure can be beneficial for the land since manure can maintain soil fertility. Manure acts as a fertilizer and recycles nutrients from grazing farm animals to crop fields, a way of returning beneficial organic matter to the land (Janzen 2011). However, with the overwhelming amount of manure produced in a factory farm, soils cannot absorb the waste at a natural pace since it is typically applied to the land at an excessive amount (Ali 2004).

"Compassion for All Beings"

The Dalziel O'Brien family found it unethical for vegans to grow crops and legumes with the use of

animal manure. While it is argued that Bruce was an early vegan-organic farmer, she recommended the optional use of animal manure suggesting that her gardening techniques were not developed for ethical reasons (Bruce 1945). Furthermore, the use of the term “Dig for Victory” and the notion of quick and cheap return for reuse of “waste garden refuge” during World War II proposes that her methods were developed and published to assist the production of British victory gardens and not in support of ending animal exploitation (Bruce 1945, p. 13). However, the Dalziel O’Brien family found potential in Bruce’s approach. They employed their vegan ideologies, arguing that manure is harmful to soil health and using manure and animal by-products supports exploitation and cruelty to animals.

One important aspect of veganic farming is cultivating without digging, which the Dalziel O’Briens employed by penetrating only the top few inches of the soil to not disturb the soil organisms in the top inches of the soil. These organisms, including worms, help bring down organic matter from the top of the soil and improve water infiltration (Vegan Organic Network 2016). It would be unethical for a veganic gardener to disturb and potentially kill these soil dwelling organisms. Some veganic farmers encourage earthworm castings in their compost. While adding worms to composts can help speed up the breakdown of organic matter, this method has been argued to be against veganic beliefs, because it uses a by-product of an animal. However, because the castings form naturally with no human intervention, some veganic gardeners will not remove castings from their farmland.

Veganic gardening has goes beyond producing food for human consumption. Guided by veganism as “an ethical stance based on compassion for all beings,” veganic farmers will purposely avoid using animals or animal by-products (Adams 2010, p. 113).

Growing Popularity

Veganic has become a marketable technique and even non-vegans are incorporating veganic

gardening into their businesses. Jack Griffin, of Metropolis Farms, describes veganic farming as “a fully-functional edible ecosystem” (Lehmkuhl 2016). In 2016, Griffin’s farm became certified by the American Vegetarian Association, becoming the first vegan-certified farm in the United States. This indoor vertical farm does not use pesticides or herbicides, recycles its nutrients and uses green manure, but uses carnivorous plants to eat the bugs that jeopardize production, a technique not commonly used in veganic farming and possibly a debatable topic (Lehmkuhl 2016). Typical veganic methods to reduce insect populations in veganic gardening is to create natural spaces that are hospitable for toads, ladybugs, birds, and other insectivores (Howard Church 2000). This may not be possible for indoor farming spaces and newer methods such as introducing carnivorous plants for controlling insects have contributed to the evolving agricultural system. Canadian company One Degree Organics Foods claims to be “the company that has popularized the term veganic” (One Degree Organic Foods 2016). While the company acquires grains from only veganic farmers, it adds honey to some of its cereals. This phase of production steers the company away from vegan beliefs, since honey is not vegan. Veganic farming is desirable for both vegans and non-vegans whether it be for animal rights, human health, or the environment.

Although vegan farming is growing in popularity, Yarbrough (2014) argues that veganic farming is not effective within global or national conventional agriculture and is most efficient at the “community level,” because on a larger scale, veganic agriculture can still contribute to soil erosion and damage the population’s carrying capacity (172). It cannot be sustainable if employed in extensive agriculture. Alloun (2015) recognizes the growing popularity and links it to veganism instead of a marketable option, arguing that veganic gardening creates an environmental consciousness within animal advocacy. She argues that veganic gardening considers “the challenges of species co-existence and ethics of place” (165) and helps us recognize and further understand the multispecies places that sustain our livelihoods.

Conclusion

With concerns about the failing environment, human health and animal rights, veganic farming is becoming an ethical mode of producing food. This form of gardening does not intentionally exploit animals, avoids chemicals and contamination of manure, and is arguably more sustainable. Veganic gardening has maintained its roots and the ideas have grown, but the initial ethical reasoning that the Dalziel O'Briens exposed have stuck through. Throughout the UK and North America, farms can become Stockfree Organic certified through soil inspections. This service was founded in 2004 by Vegan Organic Network a UK registered charity (Vegan Organic Network 2016). As of July 2016, there were four certified stockfree organic farms through this program. The Vegan Organic Network had listed 70+ noncertified veganic farms worldwide.

Veganism

Alejandra Mancilla

Centre for the Study of Mind in Nature (CSMN),
Faculty of Humanities, The University of Oslo,
Oslo, Norway

Introduction

Narrowly understood, veganism is the practice of excluding all animal products from one's diet, with the exception of human milk. More broadly, veganism is not only a food ethics, but it encompasses all other areas of life. As defined by the Vegan Society when it became an established charity in the UK in 1979,

veganism is best understood as “a philosophy and way of living which seeks to exclude – as far as is possible and practicable – all forms of exploitation of, and cruelty to, animals for food, clothing or any other purpose; and by extension, promotes the development and use of animal-free alternatives for the benefit of humans, animals and the environment” (Vegan Society 2016b).

The Vegan Society was founded in 1944 in Leicester by Donald Watson (1910–2005), his wife, Dorothy, and five other friends. But, like vegetarian principles, vegan principles have been around for much longer – for example, among adherents of Jainism who avoid doing any sort of harm to animals. Other famous vegan advocates, before the term was coined by Watson, were the British doctor William Lambe (1765–1848), who adopted a vegan diet based on health and ethical considerations, and the British poet Percy Bysshe Shelley (1792–1822), who publicly objected to the consumption of dairy and eggs.

In a recent poll, it was estimated that there are at least 542,000 vegans in Britain, a steep increase from the 150,000 estimated in 2006 (Vegan Society 2016a). In the USA, a recent study showed that 3.3% of the population declared to be vegetarian, half of which claim to be vegan – that is, around five million people (The Vegetarian Resource Group 2016).

There are two main moral justifications for veganism, both of which rely on a common assumption: that sentience, i.e., the capacity to feel pleasure and pain, is the necessary and sufficient trait to be morally considerable. (Although it is a disputed matter whether insects possess this trait or not, vegans tend to avoid the consumption of products such as honey or the use of products like silk, and generally oppose the idea of eating insects. Cf. McWilliams 2014.) In what follows, I present these two arguments and a third one which, although less popular, captures some core intuitions among vegans. I then present a challenge faced by veganism and two arguments that reject it as discriminatory, and briefly conclude.

Arguments for Veganism

The Argument Against Unnecessary Suffering

Vegans and vegetarians coincide that the human interest in nourishment and gustatory pleasure derived from consuming nonhuman flesh is largely outweighed by the interests of nonhumans in not being subject to the conditions of factory farms. Moreover, vegans accept the most influential argument for vegetarianism, known as the *welfarist argument*. This could be summarized thus:

- P1. It is morally wrong to cause unnecessary suffering to nonhuman animals.
- P2. The production process of meat and of many other nonhuman animal products causes unnecessary suffering to nonhuman animals.
- C: It is morally wrong to participate (as a producer, distributor, consumer, and so on and so forth) in the production process of meat and of many other nonhuman animal products.

The main complaint of vegans against vegetarians, however, is that the second, factual premise does not go far enough and should be replaced by the following one:

- P2'. The production process of *all* animal products causes unnecessary suffering to nonhuman animals.

This leads to the following conclusion:

- C': It is morally wrong to participate (as a producer, distributor, consumer, and so on and so forth) in the production process of *all* nonhuman animal products.

For vegans, endorsing the production process of some animal products (paradigmatically, free-range dairy and eggs) while banning others is misinformed at best and hypocritical at worst. It is misinformed at best, because it ignores the fact that even the most progressive animal-rearing practices inflict unnecessary suffering on the animals involved. For example, in free-range farms, male chicks and free-range laying hens who are no

longer productive are routinely killed, and painful debeaking remains a standard procedure. It is hypocritical at worst, because it seeks to legitimize certain forms of animal rearing while condemning others, occluding the cruelty inherent to these practices.

Depending on how they interpret P2', vegans can be divided into two groups. On the one hand, *principled vegans* believe that it is simply not the case that the rearing of nonhuman animals for food can be done in a way that causes no suffering. It is therefore always impermissible to consume all animal products. On the other hand, *contingent vegans* believe that under current conditions it is morally wrong to consume all nonhuman animal products, but this is not inevitable and could change in the future – for instance, if our patterns of consumption and modes of production changed radically.

Among both groups, moreover, there is a subset who aspires not merely to change human diets into vegan diets, but to turn the whole natural world into a vegan world where suffering is insofar as possible eradicated. Along these lines, Jeff McMahan asks whether we should gradually get rid of carnivorous species in their entirety, given that they cause so much pain to others. McMahan's point is that, "even if we are not *required* to prevent suffering among animals in the wild for which we are not responsible, we do have a moral *reason* to prevent it" – so long as our acting on that reason does not bring about worse effects than those we could prevent, like massive ecosystemic imbalances and loss of biodiversity (McMahan 2010, his emphases). This position has been identified by some as a *reductio* against the ideals of veganism.

The Argument Against Exploitation

This argument, also known as the *abolitionist argument*, runs as follows:

- P1: It is morally wrong to treat sentient beings as property.
- P2: Nonhuman animals are sentient beings.
- P3: The production process of all nonhuman animal products requires treating them as property.

C: It is morally wrong to participate in any way (as a producer, distributor, consumer, and so on and so forth) in the production process of all nonhuman animal products.

Contra welfarists, who seek to improve the living conditions of farmed animals (for example, by advocating for larger cages for factory farm hens, by demanding that more humane slaughter methods be employed, etc.), abolitionists seek a total ban on nonhuman animal production which, for them, is synonymous with exploitation. As their name reveals, abolitionists regard their quest as analogous to the quest of those who rejected human slavery: just as the latter did not demand a better treatment for slaves, but the end of the institution as such, contemporary abolitionists do not wish to better regulate the meat and animal production industry, but fight to put a definitive end to it.

Gary Francione and Anna Chorklton summarize abolitionism in six principles. First, there is no morally relevant trait that distinguishes humans from nonhumans that justifies treating the latter as property and, therefore, as having mere economic use for us. Just as treating humans as property is inconsistent with recognizing all humans as members of the moral community, treating nonhuman animals as property goes against their recognition as members of the moral community. All kinds of animal use, even *humane* ones, are thus unjustified. Second, if we recognize the right not to be treated as property, we must not seek to regulate, but plainly to abolish all institutionalized animal exploitation. It is morally wrong and practically ineffective to negotiate with factory farms *better terms and conditions* to promote animal welfare, because this will only result in them continuing to exploit nonhuman animals while making consumers more comfortable about their food choices. Third, veganism is the moral baseline for animal rights advocates, and vegan non-violent education should be the cornerstone of animal rights advocacy. There is no third path between veganism and exploitation. Fourth, the only trait that matters to be morally considerable is sentience. Fifth, all forms of human discrimination, including speciesism, ought to be rejected.

Sixth, nonviolence is the core principle of abolitionism (Francione and Charlton 2015).

Some radical abolitionists claim that at the core of their position is the idea that human and non-human animals are moral equals and have a right not to be treated as resources of others. This is why killing animals for food is always wrong. In order for this idea to gain traction, two major assumptions over which most human cultures have been constructed over centuries need to be debunked: first, that human interests are more important than nonhuman interests and that human lives are worth more than nonhuman lives. Let me present two of the most well-known arguments used to support these claims and the abolitionist's reply (Bernstein 2015). When it comes to interests, it has been typically argued that the interests of individuals who are claimed to possess rationality (i.e., humans) ought to count more than those of individuals who are claimed to lack such capacity (i.e., most non-humans). It is not the case, however, that humans consistently act on this prescription. For one thing, we do not grant a higher moral status to humans with a higher degree of rationality; for another, we do grant moral status to humans who completely lack this capacity. This shows that speciesism (the term popularized by Peter Singer to refer to our unjustifiable bias toward members of our own species) determines our moral behavior. When it comes to the value of human lives vis-à-vis the lives of nonhumans, a stock argument in defense of giving more weight to the former comes from John Stuart Mill's famous motto that "it is better to be a human dissatisfied than a pig satisfied" (Mill 2015, 124). Humans are claimed to feel both *higher* and *lower* pleasures, whereas nonhumans are claimed to feel only the latter. Among the higher pleasures that humans can feel are those connected to our future plans and projects. Nonhumans, by contrast, are always tied to their present situation. In conclusion, our lives should be valued more than theirs. But this argument is problematic. To begin with, it is not obvious why a life fully engaged in the present ought to be deemed less worthy than one always anxious about future possibilities. Furthermore, if this were the case, we should then assign more

value to the lives of humans whose life prospects are more sophisticated, but we don't – a further mark that what is at work behind these arguments is the speciesist's prejudice.

For some critics, one of the most troubling consequences of endorsing full-fledged abolitionism is that the number of farmed animals and also pets would radically diminish, eventually disappearing – the assumption being that any relationship between humans and domesticated non-humans will necessarily be exploitative. The earth's landscape in an abolitionist utopia would thus be one of stark division and limited intercourse between humans and wild nonhuman animals, where domesticated nonhumans would have gone extinct (Wayne 2013 and Zamir 2004). Another focus of criticism refers to the second and third points mentioned by Francione and Chorlton. By denying the possibility of a morally acceptable third path between veganism and exploitation, abolitionists hinder rather than promote "pro-animal strategic protest" that seeks to create better living conditions for farmed animals (Zamir 2004, 368). To the former charge, abolitionists may reply that more is not necessarily better, and that it is morally preferable to have a world with fewer, rather than more, lives that ought not to be lived. That domestication has been considered for centuries an acceptable practice is no justification for its continuation (the possibility of there being a lamb or pig raised for meat, but leading a flourishing, but short life is thus precluded). To the latter charge, meanwhile, abolitionists may respond that creating better conditions does not address the *real* problem, which is that the practice itself is wrong.

The Argument Against Negative Global Health Impacts

While less mainstream, an innovative defense of veganism refers to the overwhelmingly negative Global Health Impacts (GHIs) associated with non-vegan diets. Starting from the assumption that health, holistically understood, is the most important moral value, Jan Deckers develops a moral theory based on duties to minimize negative Global Health Impacts (GHIs) or to maximize positive GHIs, where GHIs are a unit of measurement to evaluate the effects of our actions

on the health of all biological organisms (Deckers 2011). These effects are *global* because the concept of health is holistic, encompassing all aspects conducive to flourishing, and because they take into account the consequences of our actions not only for our own health but also for the health of other existing and not yet existing humans and non-humans. The resulting prescription is *qualified moral veganism* which, while not setting a total ban on the consumption of animal products, maintains that vegan diets ought to be the default diets for the vast majority of the human population (Deckers 2016; for another version of veganism that tolerates exceptions, see McPherson 2016). To safeguard their psychological health, moreover, Deckers suggests that human moral agents should endorse *animalism*, defined as “an interest in attributing greater moral significance to either dead or living animals than to other biological organisms,” and compound it with *evolutionism*, “an interest in attributing greater moral significance to those animals biologically closer to us” (Deckers 2016). Contra those wary of being accused of defending prejudices, Deckers happily acknowledges that keeping these will help to create overall positive GHIs (which is tantamount to saying that it would diminish negative ones) and should therefore be maintained. All these ideas should be realized by the Vegan Project, a political project that aims to pass laws that would authorize the consumption of nonhuman animal products only in a very limited range of cases (Deckers 2013, 2016).

Because of his holistic definition of health, Deckers’ defense of qualified veganism highlights a moral concern with the consumption of animals who die naturally or accidentally, an issue that has been largely overlooked by advocates of the first two arguments. It also encompasses two arguments for this dietary choice that are more popular among laymen than with philosophers. One is that qualified veganism is better for human health (zoonoses, or diseases transmitted from nonhumans to humans, being one major source of concern in relation to non-vegan diets). The other is that veganism is the best dietary choice if we care about the environment, i.e., if we care about the health of the planet as a whole. If the majority of the world population stopped consuming animal products,

this would save enormous amounts of energy, soil, and water; it would drastically diminish the pollution of air and watercourses with organic and industrial residues; and it would cut greenhouse gas emissions by 18 %, more than the transport industry (FAO 2006; see also ► [Vegetarianism](#), where a similar argument is presented).

Arguments Against Veganism

Does Veganism Really Minimize Harm?

Perhaps the main moral motivation for vegans who reject the consumption of all animal products because of the suffering involved in their creation is that, through their dietary choices, they believe themselves to be abiding by what the animals rights theorist, Tom Regan, calls the Minimize Harm Principle (MHP):

... whenever we find ourselves in a situation where all the options at hand will produce some harm to those who are innocent, we must choose that option that will result in the least total sum of harm (Regan 2004, 302).

That vegans actually realize this principle, however, has been questioned. As Steven Davis pointed out in a seminal article, given the large numbers of field animals killed by industrial farming, the MHP would seem to require following not a strictly vegan diet, but rather a diet that complemented plant-based food with pasture-fed free-range cattle and their derived products (Davis 2002). Davis’s proposal – succinctly characterized as the *burger vegan view* – might be nonetheless rejected by vegans on at least three different grounds (Lamey 2007). First, not only are Davis’s empirical data extremely limited for supporting the sweeping claim he makes; these data, based on barely two studies, also do not distinguish between animals killed by their predators as a result of the harvesting process (like mice killed by owls) and those directly killed by the agricultural machinery employed. By failing to make this distinction, Davis has either to acknowledge that predation in nature is a moral evil that has to be eliminated (a contentious position defended by a small subgroup of vegans, as shown above), or else do the math again and

accept that fewer animals are directly killed by a purely vegan regime than by a mixed regime such as that proposed by him. Second, livestock farms cause harms to humans that vegan farms don't. Among such harms are the production of manure, which is a carrier of diseases such as *Escherichia coli*; a larger number of accidents among workers; dangerous jobs at slaughterhouses; and the contribution to global warming due to methane emissions (Lamey 2007, 340–41). These harms should also be taken into account. Third, Davis does not distinguish between accidental and deliberate harms, ignoring the fact that deaths caused by accident are standardly not deemed as wrong as deaths brought about deliberately. To this last point, Davis can of course reply that it is at least doubtful that deaths systematically caused by agricultural methods fit the definition of *accidental*; or, as he actually does, he can reply that deaths are deaths, no matter whether they are brought about intentionally or not (Davis 2002, 392).

If the moral relevance of the distinction between accidental and deliberate harms is rejected, a different way to defend veganism against burger veganism is to remark that what is problematic about diets that include nonhuman animal products is that they use nonhumans merely as a bodily means for the nonvital ends of others – where being treated as a bodily means requires that its body is necessary to achieve the ends of others, it does not want to be treated in that way, and the loss of well-being when treated that way greatly exceeds the loss of well-being of the others when their ends are not met (Bruers 2015, 272–73). Because the agricultural systems behind vegan diets do not require using nonhumans as bodily means, they should be preferred. It could be counter-argued, however, that not only using nonhumans as bodily means but also foreseeably harming them is morally problematic, and that, insofar as vegan agriculture foreseeably causes the deaths of thousands of mice, rats, opossums, rabbits, and other small field animals, it is not without moral blemish.

Despite its problems, the burger vegan view must be taken seriously by vegans, insofar as it suggests a different trade-off for those who wish

to comply with the MHP. Pointing out that there might be such a trade-off, however, does not go against veganism unless enough empirical evidence is gathered in its support. In the meantime, vegans can still claim that, in the face of epistemological uncertainty, abstaining from the consumption of all animal products seems like the least bad path to take if one is concerned with the minimization of unnecessary human and non-human suffering.

Meaningful Omnivorism

A common critique against veganism, also leveled against vegetarianism, is that it severs our connection with the natural world and reinforces the anthropocentric paradigm, whereby we see ourselves as superior to all other beings. Dominique Lestel, for example, argues that to avoid eating meat and all other nonhuman animal products denies our own animality and is therefore a gesture of anthropocentric superiority. Contra Regan's dictum that we should avoid insofar as possible harming others (and that this should be reflected in our eating habits), Lestel's claim is that we should instead embrace the cruelty embedded in life: to eat meat and other nonhuman animal products is to celebrate our relationship with the latter (Lestel 2014). Not everything goes, of course: like other *meaningful omnivores* (see, for example, Pollan 2006), Lestel cautions against greedy meat-eaters as well as against unconcerned ones. Just like native groups like the Algonquin in North America used every single bit of their prey and thanked it, so should we turn meat-eating into a ceremony; and just like they did not take more than needed, so shouldn't we – which means rejecting contemporary Western *hypercarnivorism*.

A Feminist Critique

Veganism has also come under attack by some feminist writers who see it as a perpetuation of the Western androcentric paradigm where adult, middle-class males in industrialized countries are physiologically privileged to attain the moral ideal (George 1994). Those who cannot opt for veganism – because it might be nutritionally inadequate (like for babies, pregnant women, and

the elderly), culturally alien (like for the Inuit), or economically prohibitive (like for some urban poor) – are *excused* by vegan theorists. By routinely excusing what they consider to be morally wrong, however, critics point out that the latter end up systematically discriminating against the vast majority of the human population. Veganism should therefore not be considered as *the* morally correct dietary choice, but one choice among many others depending on individual and social circumstances.

Conclusion

Veganism is a growing dietary choice, especially popular among young urban dwellers in developed countries. I offered three main arguments as to why one may opt for veganism: to avoid the suffering of nonhuman animals; to avoid the exploitation and, therefore, rights violation, of nonhuman animals; and to diminish the amount of negative Global Health Impacts, i.e., to best keep one's individual health, and the health of human and nonhuman others. I have suggested, moreover, that vegans who wish to abide by the Minimize Harm Principle face a challenge: given the large numbers of animals who die because of current agricultural methods, it is an open question whether pure veganism (rather than, for instance, a mixed diet of country mice killed by the plow plus vegetables) should be the morally preferred option. I then pointed to two criticisms of veganism: first, that it further separates us from the natural world, and second, that it perpetuates the androcentric Western paradigm, where adult, middle-class urban males seem to be best fitted to attain this moral ideal. All in all, the growing attention on the one hand toward what constitutes an ethical diet and, on the other hand, toward the moral status of nonhuman animals suggests that veganism will become center stage in coming discussions of food ethics.

Introduction

Vegetarianism is the practice of excluding meat from one's diet. Vegetarians avoid consuming any animal flesh, including fish and fowl. Some vegetarians eat eggs and/or dairy. Others, vegans, refrain from eating any animal products and subsist on an entirely plant-based diet, typically consisting of vegetables, fruits, grains, nuts, seeds, and legumes.

Vegetarians can also be distinguished based on their reasons for abstaining from eating meat. Some do so for reasons of personal health. Others avoid meat for economic reasons or because they have an aesthetic dislike of its taste, smell, or appearance or because their religion prohibits its consumption. But still others, “ethical vegetarians,” do so for moral reasons. In keeping with the ethical focus of this encyclopedia, the remainder of this essay will be concerned exclusively with ethical vegetarianism (also called “moral vegetarianism”).

While a great variety of arguments in support of ethical vegetarianism have been presented over the years, most of them are based on one or another of three fundamental ethical concerns. One set of arguments contends that the practice of eating meat causes the unnecessary suffering and premature death of animals and that vegetarianism better promotes animal welfare and is more respectful of animal rights. Another set of arguments maintains that meat consumption leads to poor food distribution and exacerbates world hunger, evils that would be greatly ameliorated by the widespread adoption of a vegetarian diet. A final set of arguments seeks to establish that the production of meat, in radical contrast to plant-based agriculture, leads to environmental degradation on a massive scale and is consequently unsustainable.

An Animal Welfare Argument

Perhaps the most influential argument for vegetarianism based on animal welfare considerations rests on the premise that it is wrong to cause pain to a sentient being without having a sufficient justifying reason. The claim is not that causing pain is *always* wrong but rather that it *tends* to be

wrong, all else equal, and thus requires adequate justification. While inflicting pain on others can be justified if it is necessary to do so in order to bring about some important good (as when a surgeon performs a painful procedure in order to restore a patient's health), it cannot be justified if the good to be gained is small, so that it is disproportionate to the amount of suffering it is supposed to justify, or if that good could quite easily be brought about by alternate means that would not involve the infliction of suffering. Still less can the infliction of (disproportionate and/or unnecessary) pain be justified when those who receive it do so involuntarily.

The application of this argument to the issue of vegetarianism is straightforward. On modern factory farms, meat animals are caused involuntarily to suffer terribly. The justifying reason is that people eat the animals, and this benefits human beings both by nourishing them and because of the enjoyment they get from the taste of the animals' flesh. But ethical vegetarians argue that people can nourish themselves every bit as well on a vegetarian diet as they can on a diet that includes meat and, further, that while the restrictions inherent in vegetarianism do entail the elimination of some tastes from one's diet, the vegetable kingdom still provides an almost limitless variety of satisfying and tasty eating experiences. Thus, on this view the justifying reason for the pain visited on animals is reducible to the marginal benefit in taste one can derive from including meat in one's diet as opposed to restricting oneself to plant-based foods. It appears unlikely that such a small benefit could possibly justify such a large-scale infliction of suffering.

In the past, this reasoning was sometimes challenged on the basis of the claim that meat is essential to a healthy human diet and thus that the good to be gained by causing animals to suffer is not a trivial one, but rather the vital value of good health. (George 2000 presents a variation on this argument.) But ethical vegetarians counter that there is now a scholarly consensus, acknowledged even by such mainstream organizations as the US Department of Agriculture and the American Dietetic Association, and that optimum health can be achieved while eating an exclusively

plant-based diet. Indeed, the latter organization (which changed its name in 2012 to the Academy of Nutrition and Dietetics) issued an official position statement on vegetarianism in 2009, in which it concluded that "appropriately planned vegetarian diets, including total vegetarian or vegan diets, are healthful, nutritionally adequate, and may provide health benefits in the prevention and treatment of certain diseases. Well-planned vegetarian diets are appropriate for individuals during all stages of the life cycle, including pregnancy, lactation, infancy, childhood, and adolescence, and for athletes" (Craig and Mangels 2009, p. 1266).

Another way to challenge the argument is to assert that animals are significantly less vulnerable to pain than are human beings. But this objection, too, has largely fallen by the wayside. In recent years, scientific support has been steadily growing for the conclusion that mammals and birds experience pain much in the same way that people do. Evidence supporting this conclusion comes from observation of the behavior and physiology of these animals, as well as from evolutionary theory. When animals are cut, burned, subjected to blunt force trauma, or forced to undergo other treatments that might be presumed to be painful, they tend to respond with bodily movements and vocalizations that are similar or identical to those produced by human beings in the same circumstances. These responses are muted or nonexistent when the animals have been treated with a local anesthetic, just as is the case with humans. Moreover, the more our knowledge of the underlying physiology of human pain increases, the more we find analogous anatomical structures (a nervous system and sensory receptors) in animals. Direct manipulation of these structures produces behavior consistent with the hypothesis that the animals feel pain, and neurological investigations suggest that the same parts of the brain are involved in pain processing across species. Finally, evolutionary theory points out the extraordinary usefulness and survival value of a capacity to feel pain. Such a capacity alerts an organism at once if it is being burned or cut and motivates it to remove itself immediately from this threat to its bodily integrity and well-being. This point harmonizes with the more general point

that animals benefit from having a strong and sharp sensory awareness of their (often hostile) environment. Indeed, while humans pride themselves on being more intelligent and rational than are any of the other animals, it is clear that they often lag far behind other species when it comes to the power of their senses. Hawks and many other birds have much better eyesight than humans do. Dogs greatly exceed people when it comes to the sense of smell, as do a great variety of animals with respect to powers of hearing. There is no reason to assume that the capacity to feel pain is the one sensory skill that is more highly developed in humans than in other mammals and birds.

But even if one concedes that animals are capable of great suffering, it hardly follows that the processes by which meat is manufactured actually cause such suffering. And indeed, many people assume that cows, pigs, and chickens lead safe, happy lives on family farms until they are, relatively quickly and painlessly, slaughtered. However, whatever the truth about meat production may have been in the remote past, now the overwhelming majority of meat animals spend their lives on factory farms, where the nature of their treatment is determined by economic considerations, rather than by concern for their welfare. The following is a short, and very far from comprehensive, list of the painful experiences to which meat animals in factory farms are routinely subjected.

- Most male cattle, sheep, and pigs are castrated without anesthesia. Tails of cows and pigs and beaks of chickens, all of which are sensitive body parts, are also removed without anesthesia. The reason for proceeding without anesthesia is not that factory farmers are sadists, but rather that anesthesia is expensive. (This point applies to all of the examples listed here.)
- Male chicks are of no use in egg factories. Consequently, those that are born there are immediately killed. They are thrown into plastic bags and crushed or suffocated or are tossed live into wood chippers.
- Animals are crammed into tiny cages, where they spend their entire lives, often without enough room to turn around, let alone walk or

run. Frequently, there is no (or only inadequate and infrequent) removal of feces, with the result that the animals must continually stand in their own waste.

- Dairy cows are kept in a nearly constant state of pregnancy. The resulting veal calves are removed from their mothers and fed a diet that results in anemia. The dairy cows, which would otherwise have a life expectancy of about 20 years, are fed a special diet that prematurely destroys their health but which, in the short run, maximizes their milk production. After 6 or 7 years of such production, they are slaughtered.
- Nor does the slaughterhouse provide a quick and merciful release from the horrors of the factory farm. In recent years, small slaughterhouses have given way to huge, high-speed facilities, each capable of slaughtering more than a million animals per year. Animals to be slaughtered are hung upside down and brought to the slaughterer on conveyor belts. This process frequently results in a broken leg in the case of heavy animals, such as cows and pigs. The slaughter line does not slow down for these injured animals. The animals' throats are then cut, and they bleed to death. The speed of the operation is such that before they have time to bleed out or even to lose consciousness, many of these animals experience being immersed in scalding water or having their legs cut off and their skin removed. The Federal Humane Slaughter Act requires that animals covered by the act be rendered unconscious prior to having their throat cut. But chickens, turkeys, ducks, and geese are not covered by this act, and in any case it is generally not enforced. So a great number of animals go through the throat-slitting process fully conscious. Often they must stand in line, waiting their turn, as they watch those ahead of them in line being slaughtered. Their reaction suggests that they understand what they are seeing well enough to grasp what is in store for them.

The most widespread and influential of the strategies for criticizing the argument under consideration, however, is simply to deny to animals a

moral status weighty enough to entail that human beings can ever be morally obliged to sacrifice their own interests to those of animals or to abandon traditional and customary practices out of respect for their rights or welfare. Those who take this line generally try to defend it by appealing to ways in which human beings differ from other animals. The usual tactic is to point out that animals, unlike humans, lack rationality (Aristotle 1989; Aquinas 1989), self-consciousness (Kant 1989), linguistic facility (Descartes 1989), the ability to understand the concept of a “right” (Cohen 2001; White 1989), or something else of this sort and then to argue that they therefore lack the very thing that is necessary in order to be the sort of entity that can make serious moral demands on people.

This approach has been subjected to several important objections. One, which has come to be called “the argument from marginal cases,” is based on the observation that many human beings, such as infants and those who suffer from some sort of mental impairment, may also lack whatever characteristic is held to be necessary for inclusion in the group of morally significant beings. Should moral rights to infants and to the mentally enfeebled therefore be denied? One could, of course, get around this problem by setting the bar low enough to allow all human beings in. But that would also let in pigs. One could keep the pigs out by raising the bar, but that would keep many humans out as well. To solve the problem by using inconsistent standards for humans and for animals would be to abandon the claim that one has found a standard that justifies treating the two classes of beings differently.

Critics of ethical vegetarianism have attempted to refute the argument from marginal cases in at least three ways. First is to insist that the features characteristically possessed by members of the group to which an individual belongs are of greater moral relevance than the features possessed by the individual in question, so that all humans get full moral rights by virtue of the skills and attributes of typical members of the species (Cohen 1991). Second is to suggest that we can supplement a high, individually based standard of inclusion into the realm of full moral status with

an appeal to the natural sympathy of human beings for less fortunate members of their own species (Warren 1991; Steinbock 1978). And third is to claim that it is intuitively obvious, or self-evident, that human beings are entitled to vastly greater moral consideration than are any other animals, so that no argument is necessary (Narveson 1987; Coady 1990).

But a different objection to the usual arguments against assigning significant weight to the interests of animals is that there is no obvious reason why rationality, the ability to talk, and other advanced cognitive skills should be granted such extraordinary moral importance. A more plausible candidate for this role is sentience, that is, consciousness and the ability to perceive, feel, and have subjective experiences. Notice that it is difficult to see how one could harm or violate the rights of a being that is not (and never has been and never will be) aware of anything, a being that feels nothing, and a being that has no concern about or interest in what happens to it. So sentience appears to be a necessary condition for moral standing. Conversely, it is not at all difficult to see how one could harm or violate the rights of a sentient being that cannot reason or speak. Torturing it for no good reason would seem to do the trick. Indeed, it is unclear on what grounds one could be justified in disregarding the feelings, interests, and preferences of a being that has them. So sentience appears also to be a sufficient condition for moral standing. This is not to say, of course, that it is never morally justifiable to do something that hurts someone or that goes against someone’s wishes. But it is to say that the fact that an action will hurt some entity that can hurt, or that it will go against the wishes of some entity that has wishes, is a reason of some moral weight to refrain from doing that action. One needs a justification for hurting an entity that can hurt, and it is far from clear that the entity’s lack of some higher cognitive capacity will generally count as such a justification. “Because she can’t talk, it is morally permissible to rip her skin off while she is alive and conscious”; “because he can’t reason, it is OK to castrate him without anesthesia” – these appear to be non sequiturs.

A final objection is that it makes no sense to try to justify unequal treatment of different sentient beings globally, across a wide range of different practices, on the basis of one or a small number of different characteristics that distinguish those beings from one another. The reason is that each such characteristic will be relevant only to a few different kinds of conduct but will be utterly irrelevant to others. The fact that A is a musical virtuoso and B cannot play a musical instrument at all is a good reason to treat A differently from B when both apply for a job with the local symphony, but it does not provide a good reason to treat them differently when they both show up at the hospital suffering from the same illness. Similarly, while the fact that a pig cannot read is an excellent reason not to grant it admission to study at the local university (and thus to treat it differently in this case from the human applicant who reads well), it is far from clear in what way it is relevant to the issue of whether it is morally justifiable to force the pig, unlike the literate human, to submit to the factory farm and slaughterhouse conditions described above.

A World Hunger Argument

Malnutrition is the largest single cause of death for infants and children in developing nations, killing about 14 million children each year. One argument for vegetarianism is that meat eating contributes substantially to this crisis, because animal agriculture produces food inefficiently. In order to receive just one unit of protein from meat, one has to feed a meat animal roughly 20 units of protein. (The caloric input-to-output ratio is approximately ten to one.) Similarly, it requires 20 times as much land to feed a meat eater as it does to sustain a vegan. If the same amount of grain that is fed to livestock in the United States alone were instead given to human beings, it would provide two loaves of bread per day to every person on the planet. By contrast, raising animals for food consumption requires so many resources that it would be impossible to feed the world on a meat-based diet.

Defenders of meat eating generally concede that meat is an inefficient source of protein and of calories and that a large-scale conversion to vegetarianism would substantially increase the world's food supply. But they often counter that the real problem underlying world hunger is poor distribution, rather than simply a shortage of food. Since the present system, which includes a great deal of meat eating, still generates more than enough food to go around, they argue that a call for vegetarianism is unwarranted. What is needed, instead, is simply better distribution of this already abundant supply.

Ethical vegetarians counter this rebuttal with an argument that meat eating contributes significantly to the food distribution problem. Their argument is that meat agriculture is winning the economic competition for a limited resource, namely, the world's supply of grain fields. Farmers in developing countries can make more money selling meat for export to wealthy nations than they can selling plant-based food locally, to customers who generally cannot afford meat. Thus, millions go hungry while observing that land, right where they live, is used for grazing, rather than for growing grains for human consumption. Where the demand for meat in the wealthy countries disappears, it is likely that some of the farmers in the developing nations would return to the production of plant-based food, which they would have to sell at significantly lower prices, thus facilitating better distribution to impoverished locals.

An Environmentalist Argument

Another argument for vegetarianism is based on the premise that the mass production of meat through modern factory farming methods is environmentally unsustainable. According to a report of the Food and Agricultural Association of the United Nations (2006), the livestock industry contributes on a "massive scale" to air and water pollution, land degradation, climate change, loss of biodiversity, and other forms of environmental degradation. The following is a brief and incomplete bill of particulars:

- Factory farming consumes extraordinary amounts of energy, soil, and water. For example, one needs 2500 gal of water in order to produce one pound of beef, as opposed to 155 gal to produce the same quantity of wheat. 80% of the total consumptive use of water in the United States goes to meat production.
- Factory farming leads to the introduction of toxic chemical residues into the food chain and into waterways. Farm animals produce two billion tons of waste each year worldwide, with cattle accounting for one-half of that total. Animal waste, unlike human sewage, is not treated to kill pathogens. The manure, in conjunction with the runoff of water used to clean farm buildings and equipment (plus pesticides and other agricultural chemicals), pollutes waterways, soil, and air. Meat production causes 80% of all water pollution, with animal dung alone causing twice as much water pollution as all other industrial causes combined.
- Animal waste emits methane, a greenhouse gas, which, in conjunction with the extensive use of fossil fuels in factory farming, leads to ozone depletion and contributes to global warming. Meat production accounts for more of the world's greenhouse gas emissions than does the combined activity of all vehicles of transportation (including all cars, trucks, buses, trains, ships, and planes).
- Factory farming causes topsoil loss from grazing, destruction of habitats of many species of wild animals and plants, deforestation and desertification from the clearing of land for grazing, and the destruction of ecosystems.

Many of these ecological costs of the meat industry are currently being passed on primarily to poor people in developing nations. Others seem destined to burden future generations.

Literature

There is a vast literature on ethical vegetarianism. The following is a brief and highly selective annotated list of some of the most important and influential works.

Before the word “vegetarian” was coined, in 1847, those who refrained from eating meat were frequently called “Pythagoreans,” in reference to Pythagoras, the sixth-century BCE Greek philosopher and mathematician. While none of the writings of Pythagoras have survived, several of his arguments against eating meat are quoted by the Roman poet Ovid in his epic poem *Metamorphoses*, completed in the year 8 CE.

The Greek philosopher Plutarch, in his essay of around 120 CE, “On the Eating of Flesh,” endorses the Pythagorean position and vigorously defends it against criticisms. For example, in response to the argument that eating animals is justified by the fact that animals eat each other, so that in eating them we are only treating them as they treat others, Plutarch points out that “it is certainly not lions and wolves that we eat. . . ; on the contrary, we ignore these and slaughter harmless, tame creatures without stings or teeth to harm us” (Plutarch 1999, p. 28).

The classic book-length ancient essay defending ethical vegetarianism is Greek philosopher Porphyry's *On Abstinence from Animal Food*, which appeared around 268–270 CE.

In 1892, Henry S. Salt published *Animals' Rights*, which influenced Gandhi, George Bernard Shaw, and Tolstoy, among others. Salt is also believed to be the first person to publish an article about animal rights in a philosophy journal (“The Rights of Animals,” published in *Ethics* in 1899).

Rupert H. Wheldon's *No Animal Food*, published in London in 1910, is the first book advocating veganism (though the term would not be coined until 1944).

Ruth Harrison's *Animal Machines*, appearing in 1964, is the first work to expose the horrors of factory farming.

In 1971, Francis Moore Lappé published *Diet for a Small Planet*, a best seller. It was the first major book to argue that feeding grains to animals in order to produce meat is grossly inefficient and leads to global food scarcity. She urges conversion to a plant-based diet as the best way to combat world hunger.

The single most important and influential philosophical work promoting vegetarianism and other significant changes in our treatment of

animals is the Australian philosopher Peter Singer's *Animal Liberation*, published in 1975. Singer defends vegetarianism primarily on the grounds that contemporary methods of meat production produce unnecessary suffering on a massive scale, both to animals and to humans.

Another influential book is philosopher Tom Regan's *The Case for Animal Rights*, which appeared in 1983. Unlike Singer, Regan argues that the exploitation of animals is morally wrong in principle and not merely contingently wrong because of unfavorable consequences.

John Robbins's *Diet for a New America* appeared in 1987. This book argues for vegetarianism based on the harm that meat eating causes on four fronts: animal suffering, world hunger, human health, and the environment.

The Sexual Politics of Meat, by Carol J. Adams, was published in 1990. It is the most important work criticizing meat production and consumption from a feminist standpoint.

Created from Animals: The Moral Implications of Darwinism, by philosopher James Rachels, also appeared in 1990. Rachels points out the ironic fact that many contemporary secularists, who at the theoretical level fully accept the Darwinian view that we are descended from, related to, and only quantitatively different from the rest of the animal kingdom, fail to adjust their moral views and practices accordingly and instead behave as if they accepted literally the book of Genesis's assertion that animals were put on Earth by God for the express purpose of being used by human beings.

John Lawrence Hill's *The Case for Vegetarianism*, a comprehensive treatment of ethical arguments concerning vegetarianism, was published in 1996.

Gail Eisnitz's *Slaughterhouse*, which documents that animals in major American slaughterhouses are skinned and dismembered while still conscious, appeared the following year.

Animal Rights: A Philosophical Defence, by Mark Rowlands, was published in 1998. It defends animal rights from the perspective of John Rawls's famous theory of justice. Rawls suggests that fair social policies will be the ones that we would choose if we had no way of knowing whether we, due to our particular

circumstances, would be favored or disfavored by them. The question he asks is that if we were choosing behind the "veil of ignorance," so that we did not know whether we would be born black or white, male or female, rich or poor, healthy or sick, and so forth, what social policies would we choose? Rowlands extends this approach to the question of our treatment of animals. He argues that if we did not know whether we would be born human or cow or pig or chicken, we would want vegetarianism to be the rule. The possibility of having the benefit of eating meat (if we were lucky enough to be born human) would not be worth the risk of being raised on a factory farm and then slaughtered and eaten (if we were born a cow or pig or chicken). Being a human or a nonhuman animal is not a matter of choice. So we don't deserve to exploit animals, and they do not deserve to be exploited. The current exploitative situation is unjust.

Michael Allen Fox, who had been an ardent critic of philosophical arguments for animal rights, changed his mind completely and published *Deep Vegetarianism* in 1999.

Dominion: The Power of Man, the Suffering of Animals, and the Call to Mercy, by Matthew Scully, appeared in 2002. The book is highly unusual in that, while most animal rights defenders are to be found on the liberal left part of the political spectrum, Scully is a conservative Christian – a former editor of the *National Review* and a former speechwriter for George W. Bush. He argues that the famous "dominion" passages in the book of Genesis do not license contemporary meat eating. Scully reads those passages as saying that we are entitled to use animals only if we need to and then only if we do so in as kind and compassionate a manner as possible. He then argues that, whereas many people in biblical times may have needed to eat animals in order to survive, very few contemporary people are in that situation. With regard to the second provision, he points out that nothing in the Bible anticipates that animals might be treated as they are on modern factory farms.

Food for Thought: The Debate over Eating Meat, edited by Steve F. Sapontzis, was published in 2004. It is a comprehensive anthology, which considers vegetarianism and anti-vegetarianism

from a variety of perspectives with regard to issues of health, animal welfare, and the environment.

David Kirby's *Animal Factory*, the most up-to-date book-length work on conditions on factory farms, appeared in 2010.

Future Trends

There is very little public debate or discussion about the ethics of eating meat. There is no general sense that public intellectuals or politicians are under any obligation to offer arguments in defense of slaughtering animals for food. On the other hand, the practice of vegetarianism has been on the rise for several years, and contemporary teenagers and young adults appear to be more interested in it, and more open to considering it as an option for themselves, than are people of any previous generation. These trends, coupled with the continued worsening of the world hunger problem and of threats to the environment (especially global warming), seem likely to move the issue of vegetarianism closer to the center of public discourse than it has ever been in the past.

Summary

The practice of eating meat is traditional and customary in many cultures, and it is supported by some major religious texts, including the Bible. Moreover, millions of people find significant enjoyment in eating meat. But throughout history there have always been figures who have criticized this practice and who have urged, instead, that people should adopt a vegetarian diet, that is, one that excludes meat. These "ethical vegetarians" offer three main kinds of arguments, claiming that meat-based diets, in contrast to vegetarian ones, cause unnecessary suffering to animals, contribute to world hunger, and harm the environment. While ethical vegetarians constitute a small (but steadily growing) minority of the population, it seems likely that current trends, such as the escalating degradation of the environment, the increasing global problem of

malnutrition, and greater public awareness of the treatment of animals on modern factory farms, will lead to increasing public discussion and consideration of ethical vegetarianism and of its supporting arguments.

Latin American social movements

Introduction

The Venezuelan food sovereignty movement represents an attempt by the government to establish

a national food system that strives to provide equitable food access by offering multitiered, decentralized strategies supported by legislation. The movement emerged during Hugo Chavez's period as President of the Bolivarian Republic of Venezuela. It encompasses aspects of land reform, agroecology, and distribution and is supported by principles of independence from corporate control, equality, social inclusion, shared wealth and resources, endogenous development, and participatory democracy. The food sovereignty movement represents a strategy toward greater social equality. The desire for food sovereignty arose from a history of political and economic instability that created the conditions for Dutch disease, inflation, unequal land distribution, urbanization, and poverty. While the exact outcomes of Venezuela's food movement remain unclear, its multiple strategies offer an attempt to incorporate social, cultural, and environmental ethics within a national food system.

A Brief History of Land and Agriculture in Venezuela

Venezuela has experienced many periods of political instability, dictatorial rule, and revolutionary turbulence. Colonized by Columbus in 1535, Venezuela was declared independent from Spain by Simon Bolívar on 5 July 1811. Following Bolívar's death in 1830, civilian and military leaders fought for power. During this time, *large quantities of productive land were distributed to small numbers of military rulers*. By 1937, land ownership was so concentrated that large haciendas with land holdings of often more than a thousand hectares were held by only 4.8% of the landowners (Delahaye 2003). While land reforms were attempted, land distribution remained unequal, with 5% of the largest landowners controlling 75% of the land, and 75% of the smallest landowners controlling only 6% of the land (Wilpert 2006).

The discovery of oil in 1922 transformed Venezuela from an agrarian country into one of the wealthiest countries in Latin America. Venezuela became the fifth largest oil exporting nation in the

world with the discovery of oil attributed to shaping “practically every aspect of the country, its history, its economy, its politics, and its culture” (cited by Wilpert 2003: no page). The crucial impact from oil on agriculture was the creation of “Dutch disease”: “a process whereby new discoveries on favorable price changes in one sector of the economy” (Karl 1997: 5). Foreign currency from oil exports both increased the population’s purchasing power, fueling inflation, while imported products become cheaper than domestic products, increasing the volume of imports. Cheaper imported goods flooded the market creating a consumerist society and practically destroying agricultural production while also halting industrial development. Consequently, although Venezuela has much fertile land with a range of climates well suited for diverse food production, it is the only Latin American country that is a net importer of agricultural products (Wilpert 2006).

The decline of agriculture in Venezuela drove rapid urbanization. By 1960, rural populations had declined from 70% to 35% (Quevedo 1998), and by the 1990s this number dropped to 12%, positioning Venezuela as one of the most urbanized countries in Latin America. A consequence of urbanization was the enormous slums established on the outskirts of major cities. Poverty levels increased significantly from 17% in 1980 to 65% by 1996, followed by the gross domestic product falling by 27% (Wilpert 2007). In response, the Venezuelan state *cut back* on social spending, further making agricultural production unprofitable, urbanization almost unstoppable, and compounding issues of urban socioeconomic inequality (Wilpert 2006). This culmination of poverty, food scarcity, and inflating costs came to a head in the Caracazo riots of 1989, a wave of protests, riots, and looting with an ensuing massacre that occurred as a response to neoliberal, pro-market reforms launched by President Pérez. A state of emergency was declared, placing Caracas under martial law and restoring order by force. Some say that 3000 civilians were slaughtered during this time (Maloney-Risner 2009).

Resulting disapproval with the political system led to two coup d’état attempts involving Chávez.

On February 4, 1992, Chávez launched a military coup demanding that the corrupt leadership be tried for their crimes. Their attempt failed. However, in a brief television appearance, Chávez galvanized public opinion by taking personal responsibility for what had happened and implied that he would continue the struggle for change (Parenti 2005). In November 1992, Chávez’s party attempted a second coup and failed, but this accelerated demands for impeachment of Pérez that occurred in 1993 on corruption charges (Maloney-Risner 2009). In 1994, Rafael Caldera became President and, swayed by public opinion, pardoned Chávez. However, the economic situation continued to worsen – by 1998, 80% of Venezuelans were in poverty with practically no access to healthcare, education, or any form of social service. Chávez formed the political party *Movimiento V República* (MVR) and ran for the presidency, winning on 6 December 1998 with 56.2% of the vote (Maloney-Risner 2009; Wilpert 2006).

Principles of the Bolivarian Food Revolution

Venezuela’s government remained a federal presidential republic, a participatory democracy, governed by a Constitution, with Chávez as head of state, government, and a multiparty system. The President had executive power, while legislative power was invested in the National Assembly. It was a populist government where Chávez claimed to represent the interests of common people who consisted of the majority poor. The government supported an anti-neoliberal agenda that echoed the sentiments of other Latin American governments at that time, such as Cuba, Brazil, and Bolivia. Chávez’s political goals were launched alongside the creation of a new national identity, the declaration of the Bolivarian Revolution, and, shortly afterward, the goal to create “socialism of the twenty-first century.” As part of his reforms, Chávez reframed Venezuela’s identity by harnessing the image of Simon Bolívar, who led struggles for independence in the early 1800s in Latin America. Chávez renamed

Venezuela the “Bolivarian Republic of Venezuela.” He also modified the national flag to effect symbolic change (Emerson 2011). The Bolivarian Revolution in turn represents a “major transition towards a more just political and economic system, characterized by the massive mobilization and participation of millions of people who had been historically excluded from society” (Maloney-Risner 2009: 7).

The Bolivarian Revolution is based on the principles of endogenous development, participatory democracy, and “socialism of the twenty-first century.” Endogenous development signifies “development from within,” to identify the resources and skills that already exist within Venezuela to meet the country’s needs. This principle includes revaluing previously marginalized activities, knowledge, and peoples. Participatory democracy then strives to empower citizens to play a direct role in politics, which has been facilitated in the Constitution, in the creation of laws, through the decentralization of resources, and the establishment of community councils. These principles together are said to contribute to a national state of autonomy or sovereignty enabling Venezuela to work toward becoming a nation free from corporatization, neoliberal policies, and unfair trade rules (Schiavoni and Camacaro 2009). Food sovereignty, defined by Via Campesina (2008) as “The right of peoples to healthy and culturally appropriate food produced through ecologically sound and sustainable methods, and their right to define their own food and agriculture systems,” was introduced in the 1999 Constitution.

Structure of the Food Movement

Venezuela’s food sovereignty movement is entrenched in the Constitution and supported by the establishment of the Missions. In April 1999, 92% of voters supported a referendum to create a constitutional assembly to draft a new Constitution. The *Constitution of the Bolivarian Republic of Venezuela* received approval in December 1999. The Constitution includes basic civil rights, such as freedom of expression, assembly, and

political participation; social rights, such as the right to employment, housing, food, and healthcare; and articles for extensive land and cultural rights for indigenous peoples, anti-discrimination rights, and social security benefits for women.

A number of articles within the Constitution speak directly to the right to food. For example, Article 305 states: “The State shall promote sustainable agriculture as the strategic basis for overall rural development, and consequently shall guarantee the population a secure food supply, defined as the sufficient and stable availability of food within the national sphere and timely and uninterrupted access to the same for consumers,” while Article 306 addresses rural development and support for agricultural activity. Article 307 addresses the redistribution of land, while other national laws required public and private banks to provide credit to farmers, laws for debt eradication and relief for farmers, and laws to promote agroecology as a sustainable form of farming.

In 2003, Chávez pledged to invest profits from the oil sector into the Bolivarian Missions, a series of short-, medium-, and long-term poverty reduction programs established to address macroeconomic reform, urban and rural land reform, the creation of Bolivarian schools, and support micro-credits and cooperatives. These initiatives provided a range of free and subsidized services to meet the population’s needs. Examples include education missions that teach literacy and maths, an indigenous rights mission to restore communal land titles and defend the rights of indigenous communities, and the health mission, *Barrio Adentro*, that began with Cuban support to provide comprehensive healthcare and preventative medical treatment. The overarching goal of the Missions was to reduce inflation, to diversify the economy, and to increase non-oil revenues while providing essential needs for the majority (Wilpert 2006). In Chávez’s 2011 annual address, general poverty was said to have been reduced as a result of the missions from 43.9% in 1998 to 26.7% in 2011, while extreme poverty has seen a decrease from 17.1% to 7% in the same period (COI 10/2/ 2012: 2).

Food Sovereignty Strategies

A number of missions focus on food and farming. *Misión Alimentación*, the first food-related mission, was instigated by a dramatic increase in public spending and new mobile efforts to improve food access for the Venezuelan majority. Other missions followed, including *Misión Vuelvan Caras*, *Misión Mercal*, and *Misión Zamora*. In 2011, Chávez began to condense his numerous, proliferate missions into fewer, large “Gran Misiones” to spearhead action. *Gran Misión AgroVenezuela* is one of these grand missions. Gran Misión AgroVenezuela strives to increase domestic agricultural production by encouraging rural and urban agriculture and by supporting producers in both public and private sectors. Strategies include policies of land reform, production methods of agroecology, traditional crops, and biological pest control, and the establishment of subsidized and regulated supermarkets and eateries, and free food programs.

Land Reform

Land reform is a central tenet of the Bolivarian Revolution with Chávez introducing both rural and urban land reforms to redistribute public and private land for agricultural production. In 2001, the *Law of the Land* was introduced to support *Misión Zamora* stating that all Venezuelans have a right to apply for land within certain prerequisites. This land is to be redistributed from both state and private holdings if it is more than 100 hectares of high-quality agricultural land to 5000 hectares of low-quality land. The *Law in Defense of People's Access to Goods and Services* protects the private sector but that sector must also fulfill a social function (Edwards 2016; Schiavoni and Camacaro 2009; Wilpert 2006). However, there is confusion and conflict over what is considered to be “state” or “idle” land often due to a lack of documentation of ownership. As a consequence, there has been much conflict between large land-owners and farmers, resulting in the deaths of many farmers (Ellis 2011).

The government works with farmers to warrant they have the credit, skills, technology, and marketing channels to succeed on their newly acquired land. The government institution, *Instituto Nacional de Tierras* (INTI), oversees the appropriation of the land, while *Fundación CIARA* provides credit and training. INTI and *Fundación CIARA* both form part of *El Ministerio del Poder Popular para la Agricultura y Tierras* in addition to other institutions in this sector. The rural land reform program is designed to pursue both long- and medium-term goals that include diversifying Venezuela's economy to enable the nation to both produce its own basic food necessities (long term) and to reduce rural poverty (medium term) (Edwards 2016; Wilpert 2006).

Urban land reform was also implemented, redistributing land from the suburbs to citizens as an antipoverty measure. This concept addresses multiple issues: when people acquire title to their own self-built home in the barrio, they have some security and they can then use their home as collateral for a small loan. This in turn provides the opportunity for a possible real estate market to be created that can improve the quality of the neighborhood. It is a collective process to acquire urban land, requiring 100 to 200 families in a neighborhood to first form a committee to act as a liaison with the government to acquire titles. An unintended positive consequence from this process is that land committees have then begun working on issues other than land titles, such as improving the local infrastructure, roads, access to utilities, and security (Wilpert 2006).

Agroecology, Traditional Crops, and Biological Pest Control

Agroecology was established in Venezuelan law as the scientific basis for sustainable agriculture. Agroecology works with nature to apply methods of composting, seed saving, crop diversification, and natural forms of pest control. It represents a sustainable food production method to transit away from a dependence on chemical, oil-based farming. Altieri and Toledo (2011: 588) believe

agroecology offers one pathway of resilience to climate change due to its traits of “enhancing diversity and complexity of farming systems via polycultures, rotations, agroforestry, use of native seeds and local breeds of livestock, encouraging natural enemies of pests, and using composts and green manure to enhance soil organic matter thus improving soil biological activity and water retention capacity.” Agroecology has been used on all government-endorsed urban agriculture projects from the onset yet remains a question of choice for previously established large-scale producers (Edwards 2015). A revaluing of traditional crops and farming methods is also endorsed, encouraging farmer networks to exchange agroecological knowledge and techniques. The Venezuelan government also launched laboratories to develop biological pest control agents while imposing a moratorium on genetically modified crops (Schiavoni and Camacaro 2009).

Subsidized and Regulated Supermarkets and Eateries

The proceeds from the oil sector are invested in a national, networked chain of subsidized and regulated supermarkets, restaurants, and food products to make essential food items affordable and open to people of all income levels. *Mercal* is the largest and most affordable subsidized supermarket chain. The *Mercal* supermarket emerged from the government program, *Mission Mercal*, that was partly a result of the 2002 employer-sponsored general strike that halted much of the national food distribution network. Basic essential items are sold at *Mercal* such as oil, rice, peas, black beans, lentils, sugar, meat, flour, powdered milk, and margarine. The decentralization of services is a key feature with government services often provided at multiple scales, with many outlets located in disadvantaged regions. For example, *Mercal* exists in the various forms: as different sizes of supermarkets, in mobile forms with produce delivered on trucks, held as communal markets, or as small individual points of sale distributed through neighborhood (Edwards 2015, 2016).

Alternatively, *PDVAL* is a regulated government-run chain where the government sells products directly between producer and consumer to reduce costs. *PDVAL* is a wholly owned food subsidiary of Venezuela’s publicly owned oil company *Petróleos de Venezuela, S.A.* (PDVSA). *PDVAL* was launched in 2008 with the objective to prevent the private sector from hoarding food. *PDVAL* purchases basic food products such as dairy and meat from Venezuelan and international producers and redistributes them directly to consumers at regulated prices. Both *Mercal* and *PDVAL* are part of what the government calls the “executing arms of the food policy” where *Mercal* distributes food to less poorer sectors with subsidized prices, while *PDVAL* distributes basic food to other segments of Venezuelan society with prices that are regulated and enforced. Similar to *Mercal*, *PDVAL* also has multiple forms including mobile deliveries and sales.

Another food sovereignty strategy is that of subsidized eateries that include *popular comedores* or affordable restaurants, the sandwich chain, *Arepera Socialista*, and the café and chocolate chains of *Café Venezuela* and *Cacao Venezuela*. Popular comedores provide very affordable basic meals to the public once or twice a day. *Arepera Socialista* are government-owned restaurants launched in 2009 that sell the typical Venezuelan sandwich, the arepa, at a fraction of their usual price. *Arepera Socialista* are now also mobile, serving breakfast and lunch from large trucks. *Café Venezuela* and *Cacao Venezuela* are more upmarket cafes that sell “socialist-” produced coffee and chocolate at government-subsidized prices.

Free Food

Casas de Alimentación or “feeding houses” provide home cooked, nutritious meals to pregnant women, children, and the elderly. These programs are run through a grassroots government partnership with the agency *Fundación Programa de Alimentos Estratégicos* that provides produce and kitchen equipment to community members,

who, primarily women, open their homes to feed others. Feeding houses also preferentially source produce from nearby producer cooperatives. Other “free food” government programs include the *School Feeding Program* that provides breakfast, lunch, and snacks for children in state schools and the *Law for Workers’ Nutrition* (2004) that requires workplaces of twenty and more people to provide employees with a hot meal onsite or cards that are redeemable at restaurants and food stores (Schiavoni and Camacaro 2009).

Food Sovereignty Outcomes

The death of Chavez in 2013 triggered a period of civil unrest and burgeoning food scarcity across Venezuela. This period of political turmoil obscures the outcomes achieved during Chavez’s rule and limits the expansion of the food sovereignty movement. However, protests also emphasize where improvements could be made toward achieving a more ethical and just food system.

Chávez died of cancer on 5th March 2013, and the former Vice President, Nicolás Maduro, was elected President in December 2013. Maduro has continued Chavez’s political agenda; however there have been significant criticisms of the government with widespread protests occurring across the country. Extreme political polarization further weakened Venezuela’s national economy, leading to an increase in crime, contributing to growing doubt of Maduro’s leadership ability and party policies.

However, improvements in food security were reported in earlier years. Schiavoni and Camacaro (2009) state significant increments were made in the production of corn, rice, and pork since 1998. There were also increases in beef, chicken, eggs, milk, black beans, root vegetables, and sunflowers for cooking oil, with exports of pork. This improvement in food security paralleled greater food sovereignty with outcomes attributed to the granting of land certificates, supplies and technical training for farmers to produce food, the creation of various laws, and the financing of food

production through public banking. Venezuela’s food sovereignty strategies met the first Millennium Development Goal of halving hunger and poverty ahead of the 2015 target and also cut malnutrition-related deaths in half from 1998 to 2006 (Schiavoni and Camacaro 2009). Government agencies, MINPPAL, and INN (2011) reported that boys grew 1.9 centimeters taller and girls 1.2 centimeters taller from 1999 to 2011. From 2008 to 2009, 97.3% of the population consumed animal origin proteins daily, while 98% of children daily drank milk. Infant malnutrition also fell by 62%, from 7.7% of the population in 1990 to 2.9% in 2011. However, while the population’s food consumption increased, it has not always been in the healthiest way. In recent years, there has been a transition away from cultural cuisine to western fast foods that contain high quantities of oil, salt, and sugar. A study by government institution, INN (2011) found 38% of the Venezuelan population to be overweight.

While some improvements were made, Venezuela’s food scarcity has become international news. Grave scarcity was reported of powdered milk and chicken, significant scarcity of beef, oil, white hard cheese, coffee, and sugar, and low scarcity of mayonnaise, flour, margarine, and rice. Explanations for scarcities include the hoarding of products by private enterprises as political strategies to prompt the public to lose faith in the government, the inexperience of government-established cooperatives to run enterprises effectively, and the government’s regulation of food prices resulting in producers not receiving sufficient pay (Edwards 2015). Food sources from government enterprises also contribute to food shortages. For example, while Mercal stocks some domestic produce, much of what they sell is imported.

Problems are also experienced at the level of production. While the government promotes a range of innovative, urban agriculture options for community participation, uptake remains slow. Factors include repercussions from Dutch disease and cultural issues such as individualism and an expectation of government handouts rather than actively seeking to collaborate in community

initiatives. As a consequence of food *insecurity*, many citizens are buying and hoarding large quantities of supplies, resulting in stores very quickly running out of stock (Edwards 2015, 2016).

Venezuela's continued reliance on the petroleum also causes issues with fluctuating international oil prices creating extreme inflation while also impacting the environment and culture, polluting natural resources with peopling losing connection to the land and food production. Oil's influence on politics has also created a very bureaucratic state where it is almost impossible to get anything done, let alone trying to push ahead something that is new and different (Edwards 2015, 2016).

Conclusion

The food sovereignty movement is a central component of Venezuela's political transformation toward "socialism of the twenty-first century." It has contributed toward building a new socioeconomic state by restructuring not only the relations of production, distribution, and consumption but also the social ownership of production. These changes are based on principles of social equity and justice. The Venezuelan food sovereignty movement has demonstrated that it is possible to improve aspects of domestic production and distribution to benefit the majority poor. However, ongoing issues from history combined with recent political polarization, crime, inflation, bureaucracy, and nationwide unrest have threaten food supply in the short term, causing extreme food scarcity that together place in doubt the future of Venezuela's food sovereignty movement.

Vertical Farms in Horticulture

Dickson Despommier
New York, NY, USA

Synonyms

Plant factories (Japan); Sky farming; Skyscraper farming

Introduction

Vertical farms are multistory buildings containing an environment conducive to the growing of fruits, vegetables, and nonedible plants for things such as biofuels, drugs, and vaccines. Vertical farms take advantage of the same technologies that enable high-tech greenhouses to flourish. Vertical farms (VFs) are a form of controlled environment agriculture (CEA).

Since the 1990s, with the development of sophisticated hydroponic, and to a lesser extent aeroponic growing systems, CEA has matured into a commercially viable strategy for the large-scale production of a wide variety of crops (Practical Hydroponics and Greenhouses 2005). Historically, attempts to grow large amounts of vegetables and fruits indoors failed to evolve into commercially successful businesses, due largely to the lack of reliable technologies for growing plants hydroponically. Dr. William Gericke is given most of the credit for improving and further developing hydroponics in the 1930s while working at the University of California, Davis campus (Gericke 1940).

Hydroponics is the science of raising plants in the absence of soil. It typically employs a tubular growing system (usually constructed out of PVC piping) for holding the plants, which delivers a thin film of dissolved nutrients to the roots that are in contact with the liquid phase of the system. Today, hydroponic greenhouses have become highly viable economic ventures. They offer many advantages over traditional outdoor farming practices, the most important being total control of

the physical and chemical conditions necessary to insure optimal plant growth and maturation: day/night cycle, temperature, humidity, soluble growing media (e.g., nutrient film technologies), aeration of root systems, pollination, and even quality of taste. By employing CEA with hydroponics on a large scale, many vegetables (e.g., tomatoes, cucumbers, melons, strawberries, green beans, peppers, and a host of leafy greens) are being grown under near ideal conditions, giving maximum yields in shorter periods of time to maturity following germination of seeds, compared to current outdoor farming strategies. In some extreme cases (e.g., lettuces), as many as eight crops a year can be harvested by indoor hydroponic technologies, compared with just two to three from outdoor farming operations (<http://www.androidworld.com/prod26.htm>).

Indoor crop loss is typically less than 10%, whereas in most situations employing the most up-to-date equipment and methods, crop losses from traditional methods, from time of planting to harvest, can be 50%, with losses in developing countries exceeding 70% (<http://www.fao.org/docrep/008/y5800e/Y5800E06.htm>). Since many greenhouse facilities are located on the outskirts of their markets, food miles are greatly reduced, which helps to reduce loss of produce due to manipulation of the harvested plant during the shipping and handling phase of getting it to market. Finally, since none of the plants are grown in soil within hydroponic greenhouses, this approach to food production offers the distinct advantage of being able to be carried out anywhere in the world.

The Rise of Indoor Farming

Greenhouses have existed since the early 1700s, apparently having first originated in England as enclosed wooden structures (http://www.nvsuk.org.uk/growing_show_vegetables_1/origins_greenhouse.php). The advantages of greenhouses were immediately apparent to those lucky enough to have benefitted from living near them, and the idea rapidly evolved into today's modern transparent marvels of agricultural ingenuity. Soil-based agriculture was the first method used in them, and

various flowers (e.g., roses, orchids) were the most commonly grown plants until hydroponics expanded the repertoire to vegetables, fruits, and herbs.

Since the 1990s, many commercial greenhouses have become equipped with a wide selection of computer-assisted monitors, rheostats, and pump systems for delivering water and nutrients, insuring optimum conditions throughout each plant's growing cycle, from germinated seedlings to harvestable crops. Europe, North America, Australia, Japan, Korea, and China have thriving greenhouse industries, inside of which are grown an astonishing variety of edible plants. Lagging behind in greenhouse development and implementation are countries throughout Central and South America and sub-Saharan Africa. Unfortunately, in many of these latter places, especially Africa, greenhouses are sorely needed to help offset the often staggering annual losses of crops due to inclement weather, poor soils, arid environments, and hordes of insect pests, such as locust.

One of the largest commercial greenhouse operations (318 acres) is EuroFresh Farms, located in the desert near Wilcox, Arizona (<http://www.eurofresh.com>). Another unlikely place for growing crops indoors is the urban landscape, but even here good examples of commercial greenhouses can be found, such as Bright Farms (<http://www.brightfarms.com>) and Gotham Greens (<http://www.gothamgreens.com>), both of which are based in New York City.

Thus, if growing food in greenhouses employing state-of-the-art technologies and locating them within a large city, such as New York or London, makes sense from an economic perspective, then why not increase proficiency and output by extending their vertical footprint into several stories worth of production space? That is the essence of the concept of a vertical farm (VF). In fact, that is exactly what is happening in many places throughout the developed world.

Rationale for the Vertical Farm

The idea of growing food crops in tall buildings is not new, most likely originating in ancient times

with the hanging gardens of Babylon as a prime example. Nonetheless, growing things that people can eat in that configuration was not forthcoming until recently. The reasons why the idea of vertical farming has taken so long to develop probably relates to the relative ease of farming outdoors in soil. Simply plow up some flat, already fertile land (preferably near a large river), then sow the seeds. Pray for rain, but not too much. Pray for moderate temperatures. Pray for no plant pests or diseases, too.

Agriculture arose in many places, but the most famous one was along the Nile River in Egypt. The Egyptians turned a non-systematized scheme of planting and harvesting, invented by the inhabitants of the "Fertile Crescent," into a well-defined science, keeping track of virtually everything that was important in order to insure a good yield. They paid very close attention to the annual rhythms of the Nile. At the same time as the Egyptian dynasties of the upper Nile rose to power, the humble dung beetle became elevated to the status of a revered God, because from where the average Egyptian stood, this lowly creature was observed turning animal waste into an edible plant simply by digging a hole and stuffing a ball of rolled up dung into it! Moreover, another dung beetle emerged along with the new plant the following spring, giving this insect the appearance of being able to create new plant life and live forever. In contrast to the first farmers in the Middle East, Egyptians used animal dung as fertilizer, in addition to the new soil brought to the upper regions of Egypt by the annual flooding of the Nile. The Egyptians became the first people to practice biomimicry (i.e., looking to nature for solution to their problems). But just as in all the other locations at which agriculture arose (e.g., China, Mexico, Borneo), crops occasionally failed, for a multiplicity of reasons. Soon thereafter, the need for Gods (e.g., Osiris, Kokopelli, Hermes, Saturn) that could intervene with these unwanted agricultural outcomes arose, and the incantations recited to elicit their help became a regular part of every farmer's vocabulary. Luckily, today's indoor farmers have little need for invoking the blessings of such Gods. Mostly, they pray for lower rates on their electric bills and a guaranteed market for their crops.

The Rise of the Vertical Farm

Throughout the millennia that followed the invention of agriculture (about 10,000 years), traditional farming technologies advanced slowly or not at all. It was not until the chemical synthesis of artificial nitrogen-based fertilizers, made possible by the Haber-Bosch process (Balken 1997), which took atmospheric nitrogen and combined it with hydrogen to make ammonia, and the synthesis of a wide variety of agrochemicals for controlling weeds, insects, and microbial plant diseases (Müller 2000) that the post-World War II global farming community began to produce more food than the world could consume. As the human population burgeoned under this new agricultural revolution, more land was placed into the production of crops that were destined to feed animals or for the production of value-added products like high-fructose corn syrup and a wide variety of soy-derived products.

Over the next 50 years, aggressive application of agrochemicals to the land, including pesticides, herbicides, and fertilizers, became a regular feature of farming in the developed world. Eventually, agricultural runoff, laden with silt and agrochemicals, began to have a negative effect on the land, with birds (raptors in particular) being the most obviously affected by the overuse of DDT (see Rachel Carson's book, *Silent Spring*). In many cases, nutrient-rich runoff also drastically reduced the harvest of sea life from estuaries around the world by encouraging algal blooms that depleted the oxygen in the shallow waters of those fragile ecotones. In addition, an accelerating rate of climate change began to alter traditional patterns of weather, adversely impacting the world's agricultural community, resulting in numerous crop failures due to floods, droughts, and untimely monsoons. By the 1980s, the cause of the increased rate of climate change was obvious to most – increased levels of greenhouse gasses in the atmosphere due to the burning of fossil fuels. Even many of the most outspoken skeptics of the causes of climate change came to admit that the data were overwhelmingly in favor of the conclusions reached by the Intergovernmental Panel on Climate Change (IPCC).

As a direct result of the fourth report on climate change issued by the IPCC in 2007 (IPCC 2014), viable alternatives to traditional methods of growing food (permaculture, hydroponics, aeroponics, aquaculture) began to gain traction as practical approaches to augmenting dwindling food supplies due to crop failures caused by severe droughts and floods. In the 1930s, Buckminster Fuller suggested the possibility of farming in skyscrapers, as did John Todd (<http://www.toddecological.com>) later in the 1960s, although their suggestions were ignored. It is probable that this was because it was not obvious during 1960 that outdoor farming would be in serious trouble, especially in the United States. By the year 2000, all that had changed. In 2008, just a year after the IPCC report forecasted dramatic changes in the world's food supply, some countries (e.g., Korea, Singapore, Sweden) were politically and financially able to support a demonstration program designed to bring about a paradigm shift in the way they managed their food supplies, including the construction of VF.

Vertical Farms: Anticipated Advantages

There are numerous advantages to farming indoors in the modern greenhouse, and the VF improves on the theme of the high-tech greenhouse in several ways. First, it immediately increases the yield per acre of any crop by multiples based on the number of floors the VF has. A typical greenhouse can out produce a similar-sized outdoor farm for the same crop by a factor of anywhere from 4 to 10, depending upon the specific crop in question (personal communication, Gene Giacomelli, director of the CEA program at U. Arizona). By doubling or tripling the growing space in a VF, this factor will also go up accordingly.

Second, having VFs inside the city limits can result in a significant reduction in food miles (i.e., the distance between the place that produces the food and the places where it is consumed) (National Resource Defense Council 2007). Shortening that distance will save on the use of fossil fuels and lower the amount of greenhouse gasses in the atmosphere. Each year, traditional

farming in the United States consumes some 10% of the fossil fuels (Heller and Keoleian 2000). As VFs come on line and gain in popularity, it is hoped that one of its intended consequences will be to significantly lower that percentage.

Third, VFs contribute to job creation. A plethora of activities are required at many levels to insure that the VF functions at maximum efficiency: managing the seed germination facility (e.g., nursery), transplanting seedlings into the VF, procuring and managing resources (e.g., water, nutrients, growing systems, lighting systems, automation, etc.), monitoring plant growth and development, developing pollination strategies, harvesting, distributing the harvest to local green grocers, and managing waste-to-energy protocols and quality control (DNA-based laboratory surveillance for plant pathogens and arthropod pest control). Other job requirements include IT personnel, human resource management, and business office personnel. These are but a few of the more important tasks awaiting a new work force in the newly emerging vertical farm industry. Community outreach, education, and a business center could also be considered after the basic operations of the VF become established.

Fourth, if and when urban agriculture in all its variations, including rooftop greenhouses and stand-alone VF facilities, becomes the norm for supplying the bulk of fresh fruits, herbs, and vegetables to those who choose to live in cities, then some land currently dedicated to farming could be allowed to return to its original ecological setting. In most cases, this means the reforestation of hardwood forests (<http://www.hubbardbrook.org>) that once stood where fields of corn and soybeans now grow. If enough land could be restored by benign neglect, then trees would once again become an important factor in the sequestration of atmospheric carbon dioxide (Ross 2009). This could have a significant impact on the rate of climate change, slowing it down enough to allow more time for us to adjust to the inevitable rise in the Earth's temperature. This might seem like wishful thinking to some, but if nothing is done to reverse deforestation (Ross and Pervaze 2010), then the Earth will soon be stuck

with a runaway climate regime, for which there is no solution.

Finally, food-borne illnesses due to contamination of harvested produce (e.g., listeria, salmonella, *E. coli* strain 0157) can be avoided by employing clean technologies linked to indoor farming. Furthermore, the lack of direct contact of harvested produce with farm animals using CEA greatly lessens the chances of contamination during the shipping and selling of crops grown indoors.

In the beginning, VFs will undoubtedly be very expensive to construct, own, and operate, with operating costs strongly linked to energy use. As more come on line, however, these costs will decline in all aspects of construction and operation, including the most daunting single item, energy requirements, for operating them. This is particularly relevant with respect to the amount of electricity needed to power LED grow lights. Today, the most efficient LED systems that produce both red and blue wavelengths of light are around 28%. Experts in the field of high-tech greenhouse science estimate that this percentage needs to be around 60% efficient to encourage the average venture capitalist to invest in a vertical farm. At that level of energy efficiency, profitability is clearly a real possibility. As an aside, the theoretical limit of efficiency for LED light is an astounding 100%, so expectations are high that the magic number of 60% efficiency is only several years away from the consumer market.

Existing Vertical Farms

In 1999, the idea of farming in tall buildings was taken on as a subject in a class taught at Columbia University. It evolved within a few years into an annual classroom exercise, exploring all the major issues associated with making vertical farming practical. The projects resulting from that course were posted on the Internet (<http://www.verticalfarm.com>) and received a large number of submissions for designs of vertical farms, many of which were added to the web site (see Google Images – Vertical Farm). In 2010, a book was published on the subject, *The Vertical Farm*

(St. Martin's Press, New York), even though there were no vertical farms up and running at that point. Within a year, however, vertical farms had become a reality in Korea, Japan, Singapore, and the United States.

Republic of South Korea

The vertical farm established in Suwon, Korea, in May of 2011 is financed by the South Korean governments' Rural Development Administration and operated under the leadership of Choi Kyu-hong (www.youtube.com/watch?v=83f_q_9yW5k). Construction was completed in March of 2011. It is three stories tall (Fig. 1) and grows mainly leafy green vegetables. It derives 50% of the energy needed to support a robust LED grow light system (Fig. 2) from an array of solar panels located along the side of the building and a supplemental geothermal system. The VF features an automated rack system for moving plants from the top of the VF to the harvesting area. The VF has two main functions. Its primary mission is to serve as a research facility to further the general development of the concept of vertical farming and to improve the energy efficiency of indoor farming

in multistory buildings. Its secondary goal is to serve as a site for testing the viability of various seeds that are stored in the much larger national seed bank building (Fig. 3) located adjacent to the VF.

Japan (Kyoto): Nuvege

Nuvege is a commercially successful "plant factory" housed in a single, very large building that resembles a 747 passenger jet hanger (Fig. 4) (www.nuvege.com). It occupies some 30,000 horizontal square feet, but within that space, Nuvege utilizes over 57,000 square feet of vertical growing space. LED grow lights and hydroponics are used in combination to produce leafy green vegetables of several kinds. They are currently expanding their Kyoto operation to include vertical farms in Tokyo and some as yet unspecified locations within the United States.

There are many other "plant factories" scattered throughout Japan. As of 2012, there were an estimated 50 such facilities, with over half of them taller than one story in height. Many more are planned over the next several years.

Vertical Farms in Horticulture, Fig. 1 Vertical farm in Suwon, Republic of South Korea

Vertical Farms in Horticulture, Fig. 2 Inside the vertical farm in Suwon. (Note the abundant use of LED grow lights)

Vertical Farms in Horticulture, Fig. 3 National seed bank of Republic of South Korea in Suwon

Singapore

Sky Greens (www.skygreens.com) is a commercial vertical farm located in Singapore that produces leafy green vegetables (www.youtube.com/watch?v=yHkYp_az7Iw). Jack Ng started the building prototype in 2009 as a public-private partnership between Sky Greens and the Agri-Food and Veterinary Authority of Singapore.

Chicago, Illinois: The Plant

The Plant is a three-story vertical farm located within the city of Chicago (Fig. 5) (<http://www.plantchicago.com>). It is housed in a retrofitted abandoned meat processing (smoking bacon and related products) plant that produces a wide variety of edible crops and tilapia. Plans are in place to install an efficient waste-to-energy system using biogas from an anaerobic digester. According to its executive director, John Edel, The Plant should be off the energy grid of Chicago once the digester is up and running sometime in 2013.

There is a large vertical farm complex on the campus of Texas A&M University, sponsored by DARPA and operated by the Texas Plant-Expressed Vaccine Consortium. It grows genetically engineered tobacco plants to manufacture virus like particles for use in an influenza vaccine (see and listen to This Week In Virology, episode

Vertical Farms in Horticulture, Fig. 4 Nuvege vertical farm, Kyoto, Japan

Vertical Farms in Horticulture, Fig. 5 The Plant vertical farm in Chicago

47, Vertical Vaccine Farm, for details as to how this system works). It can produce some 1, 500 doses of vaccine from a kilogram of plant material. Commercial vaccine producers use chicken eggs for the same purpose. Each egg yields only one dose of vaccine. The advantages of such vertical farms for the production of other products useful in human medicine (e.g., insulin, antibodies of varying specificities, clotting factors) will become more obvious as the need for these

products becomes more acute over the next 20 or so years.

Planned Vertical Farms

In 2012, Plantagon (www.plantagon.com), a private corporation owned and operated by the Onondaga Nation of New York state (www.onondaganation.org), announced plans to build a

17-story version of a vertical farm in the town of Linköping, in southern central Sweden, in collaboration with the Swedish government. Ground-breaking, began in the spring of 2012, kicked off this ambitious venture. It is not known how long it will take to complete the building, but it will probably be finished within a year. Plantagon intends to grow many varieties of Asian leafy green vegetables as their initial commercial offering to the consumer.

Jackson, Wyoming

Vertical Harvest plans to construct a three-story vertical farm in Jackson, Wyoming (www.verticalharvest.org). They are in fund-raising mode as of September 2012. Their goal is to raise enough funds to qualify for a Wyoming business grant. If they succeed, they plan to grow tomatoes, strawberries, lettuce, and micro-greens. Vertical Harvest is a for-profit corporation.

Summary

The concept of vertical farming has already evolved from a classroom activity in 1999 to the construction of vertical farms. It is anticipated that as Earth's climate continues to change over the next 20 years, adversely altering the global agricultural landscape even further, the establishment of large numbers of indoor farms inside the city limits will become a significant contributor to the urban food supply. When this occurs, then food-borne infectious disease outbreaks and food shortages will be greatly reduced.

Vertical Integration and Concentration in US Agriculture

Mary K. Hendrickson¹, Harvey S. James Jr.^{2,1} and William Heffernan¹

¹Division of Applied Social Sciences, University of Missouri, Columbia, MO, USA

²Department of Agricultural and Applied Economics, University of Missouri, Columbia, MO, USA

Synonyms

[Consolidation](#); [Globalization](#); [Industrialization](#)

Introduction

Vertical integration is the process whereby one firm merges with another firm from which it

buys inputs or to which it sells output. Concentration reflects the degree of horizontal integration and defines the extent to which a firm has competitors. The food system in the United States has become increasingly integrated and concentrated during the last 100 years. Economists have long argued that economic factors – most notably economic efficiency – largely explain the increase in vertical integration and concentration in the agrifood industry (MacDonald et al. 2004), but others implicate the exercise of market power and changes in antitrust policy enforcement as explanations (Carstensen 2008; Hendrickson and Heffernan 2002). Concentration and integration (hereafter simply “consolidation”) in the food system raise a number of important ethical issues for farmers, agribusiness firms, and consumers. These ethical issues are derived from the fact that concentration fundamentally defines and limits the choices or options for most people. Everyone eats and thus has a stake in the food system, but many people also work in the food system providing labor, management, and capital. It is how members of society respond, or are forced to respond, to limited options that form the basis for many of the ethical problems we observe in the food system. This entry describes the trends in consolidation within the agrifood industry and highlight a number of important ethical issues and their implications arising from industry concentration.

Trends in Agrifood Consolidation

There are many ways to describe the degree to which an industry is concentrated. A common method is to examine the industry’s four-firm concentration ratio (CR4), which measures the total percentage of a market controlled by the industry’s four largest firms. Scholars have documented extensively the increase in concentration in virtually all sectors of the food and agriculture industry (see, for instance, Hendrickson et al. 2002; Howard 2016; MacDonald 2016). For example, in 1967 the four largest firms controlled one-quarter of the

non-poultry animal slaughtering industry, but by 2007 that share more than doubled. In wet milling, the four largest corn milling plants controlled 68% of the market in 1967, but by 2007 that share increased to 83%. Similarly, the four largest flour milling firms controlled 30% in 1967, but increased their share to 55% in 2007 (see James 2013a for source details).

Table 1 presents the CR4 for several agricultural and food retailing markets in the United States, as well as names of the top firms if known, for a roughly 25 year period between 1990 and 2016. The table reveals several important patterns. First, with one exception (flour milling), the food sectors represented became more concentrated – meaning the top four firms controlled a larger share of the market. Second, the increase in concentration can occur relatively rapidly. For example, the pork production capacity of the four largest firms nearly doubled in a 10 year period of time. Third, some firms dominate multiple sectors and thus represent both industry concentration as well as vertical integration. Cargill, for instance, produces and processes an array of meats, provides feed and trades/processes corn and soybeans. Tyson is able to provide a full array of protein – beef, pork, and broilers. Finally, the four largest firms are not the same over time. Some firms dominating their sectors in 2011 or 2016 were not present in 1990, thus illustrating how quickly firms can come to dominate their industry (e.g., JBS in protein and Wal-Mart in groceries).

While the market shares reported in Table 1 reflect the reality of the markets that farmers face when they try to sell their products, concentration has also occurred extremely rapidly within agricultural inputs, specifically in fertilizers, chemicals, and seeds. Changes in the input sector have occurred rapidly in the last two decades partly due to the introduction of propriety agricultural biotechnology. The introduction of herbicide tolerant crops in the mid-1990s spurred rapid consolidation among seed companies and convergence between seed and chemical companies (Howard 2009). Fuglie et al. (2011) estimated a concentration ratio for the top four firms (CR4) of 54% of global commercial seed market, with

certain segments even more concentrated (e.g., the global vegetable seed market has a CR4 of 70%, while in the late 2000s the CR4 for the US cottonseed, corn seed, and soybean seed were all over 50%). Consolidation in this sector is not stopping. Between 2015 and 2017, major mergers between the largest seed and chemical companies have either been proposed or approved, including Bayer's proposed acquisition of Monsanto, and a merger between Dow-DuPont. If these mergers are completed, the new firms are estimated to control half of the global commercial seeds market (see Table 2).

Because of the convergence between seeds and chemicals, mergers impact the agrochemical market as well. ChemChina recently acquired Syngenta, which was the third largest global seed company and largest agrochemical company with over one-fifth of the global market in 2011 (ETC Group 2013). Without any divestitures (that are sometimes required for mergers to proceed), just three firms will sell 70% of agrichemicals globally based on their 2011 sales (see Table 2). In the fertilizer arena, six global companies (Yara, Potash Corp, Agrium, Mosaic, OCP, and a Russia-based potash cabal) dominate (Taylor and Moss 2013), with over half the market for phosphorous controlled by two, and three-fifths of that for

potash controlled by three. In 2016, Potash Corp and Agrium announced merger plans to create the largest fertilizer company in the world.

As one can see from these mergers, consolidation and concentration are global phenomena. Along with Wilkinson (2002), who documents concentration in Brazilian markets, De Schutter (2010) claims that five grain traders dominate the soybean processing market in Brazil, while a CR2 of 53% in dairy processing in the mid-1990s caused the collapse of dairy farmer cooperatives. Moreover, since the early 1990s, there has been a rapid increase in the globalization of the protein and grain markets. In this context, globalization refers to the process by which firms come to dominate similar markets but in different countries and geographic areas. For instance, in the 1990s ADM invested heavily in soybean processing facilities in Paraguay, Uruguay, Brazil, and China (see Heffernan et al. 1999; Hendrickson et al. 2008a). Cargill operates significant enterprises around the globe with grain trading activities in all major ports and significant processing facilities in China, where ADM, Bunge, Cargill, and Louis Dreyfus have become the largest soybean processors (Peine 2013). Constance et al. (2013) noted that Tyson has significant meat operations in Mexico while Smithfield

Vertical Integration and Concentration in US Agriculture, Table 2 Global seed and agrichemical companies

Seed company and global rank on global seed sales	Concentration ratio of global proprietary seed market (current)	Merger partner	Percent of global proprietary seed market of combined firm (estimated)

operates pork facilities in Brazil and Eastern Europe; the latter occurred at the same time as rapid expansion and consolidation domestically and internationally. US firms are not the only dominant players either. JBS, based in Brazil, is currently the world's largest beef packer, while Smithfield, the largest US pork processor, is owned by a Chinese firm with significant ties to the Chinese government (Howard 2017).

The processes of horizontal integration and globalization have also been very apparent in food retailing. In the 1990s, the food retail industry in the United States consolidated rapidly, primarily due to Wal-Mart's entry into groceries in the late 1980s. By 2000, Wal-Mart was the second largest grocer in the United States (Hendrickson et al. 2002) and is now the dominant firm (see Table 3). According to the *New York Times*,

Wal-Mart has over three times the sales of its nearest competitor (Clifford 2011).

Wal-Mart is one of a small number of emerging global grocers that include Carrefour (a French firm that is the second largest general retailer in the world) and Tesco, Britain's largest grocer. Understanding the global reach of food retailers is important because of their control over global supply chains that source food as cheaply and consistently as possible. As Lynn (2006, 2009) notes, Wal-Mart tends to use its market power as a retailer as a tool to negotiate lower prices to producers, manufacturers, and workers rather than forcing consumers to pay higher prices.

Ethical Issues Resulting from Consolidation in the Food System

One of the primary implications of consolidation is that it limits choices in the marketplace. Importantly, the ethical issues that arise because of consolidation are not unique to the food system, as any industry that consolidates creates constraints on existing participants. However, the ethical consequences of concentration in the food system arguably become more important than that in other goods and services because everyone must eat – and on a regular basis. Food is a necessity, which means that the constrained choices of the market can rapidly become a life or death situation in terms of hunger and nutrition. This means that those with more options, or those with greater control over their choices, may actually bear some responsibility for the fates of others. There has been a growing debate among scholars and policymakers about the implications and ethics of industry concentration (see, for instance, James 2013b). The following highlight a number of these ethical issues.

Because industry concentration and integration have been occurring in both farm input and farm output sectors, farmers can feel the effect of constraints the strongest. Hendrickson and James (2005) argue that consolidation has two important and direct effects on farmers. “First, it constrains – as in limits or inhibits – the decisions of farmers by restricting choice options or the types of

decisions they can make. ... Second, it constrains – as in compels or obliges – the choices of farmers by forcing them into the kinds of decisions that they otherwise would not have chosen for ethical or other reasons” (p. 283). Both of these effects can increase the economic pressures that farmers feel and, as a result, create tensions on or even produce an erosion of one's personal ethics (see Hendrickson and James 2005; James and Hendrickson 2008). Constrained choice also has an environmental impact, as it affects how farmers care for, treat, and otherwise manage land. As Stuart (2009, p. 53) finds, “consolidated markets and increasing corporate power in the food system can constrain producer choice and create ethical dilemmas over land management ... [in that] growers face serious ethical dilemmas and feel pressured by large processing and retail firms to adopt measures they find environmentally destructive and unethical.”

The trends in consolidation noted above also raise the ethical question of whether there is adequate and fair competition in agriculture. For example, in 2010, the US Departments of Agriculture and Justice held a series of workshops in the United States on the issue of agricultural competition. In these workshops farmers and agricultural producers were invited to voice their opinions on what they perceive as the nature of competition in the agrifood industry. Speaking in the opening session, US Attorney General Eric Holder said, “Is today's agriculture industry suffering from a lack of free and fair competition in the marketplace? That's the central question” (USDOJ-USDA 2010, p. 11). Important in this discussion is how adequacy, fairness, and competition are defined (see James 2013a; Thompson 2013; Sykuta 2013) as well as the extent to which economic concerns about efficiency, which economists argue have driven the rapid consolidation in agricultural markets, is compatible or in conflict with moral obligations that industry participants have toward each other, animals, and the environment (Rohwer and Westgren 2013).

Industry consolidation in the food sector also raises concerns about how economic power is

shifting toward fewer and larger firms and how such power is not being held in check by countervailing economic, social, or political forces (Levins 2002; Taylor and Domina 2010). For example, James et al. (2013) show how the changing structure of the food sector can increase the dependency that some market participants have on others with whom they buy and sell. Importantly, they show how dependency, defined as being reliant upon someone or something else, cannot always be determined by considerations of industry concentration alone (e.g., by measures of CR4). The reason is that focusing on the market share of the top firms obscures the myriad sets of relationships that farmers, food processors, and others are embedded in when they buy inputs or sell their finished products. These relationships can have their own sets of local dependencies which create or transmit power imbalances along value chains. Thus, “entities who rank near the top in CR4 can experience significant dependency advantages on the buying end (e.g. beef packers with a CR4 of 82% [may extract concessions from farmers and feedlots]) but when selling, the power resulting from differential dependencies is dissipated by the fact that other entities may possess significant buying power relative to them (e.g. Wal-Mart with somewhere between a quarter and one-third of the grocery market [buys beef from the packer and extract concessions from them])” (James et al. 2013, p. 121).

Food consumers, especially those who consider themselves “ethical eaters,” also face ethical dilemmas resulting from consolidation. The lack of transparency in the current food system, where the vast majority of food moves through supermarket and food service outlets, means that it is difficult for consumers to find out how their food was produced, who produced it, and where. These consumers may want to buy foods produced in ways that match their environmental and social values but with their limited range of choices – if such foods are available at all – they cannot act on their own personal ethics. Moreover, there can be a lack of trust that the food standards and labels used to define their choices really reflect their core values, given the negotiations that occur between farmers, supermarkets, and third-party

(independent) certifiers of standards such as humane, sustainable, fair labor, or fair trade (Hatanaka et al. 2006).

The “ethical eaters” described above are often portrayed as elitist and misguided (McWilliams 2009; Lusk 2013). However, they most likely possess the money and knowledge necessary to participate in the existing food system markets – or leave them altogether for new forms of procuring food such as personal production or direct connections with farmers or processors who farm and produce food in ways compatible with their ethical interests. But many social justice and public health advocates have raised concerns about the quality and quantity of food available to the most vulnerable citizens of society, those who live in areas, either rural or urban, without good access to fresh, healthy, and safe food with perhaps too much availability of cheap, highly processed, and unhealthy foods (Ver Ploeg 2009; Story et al. 2008). These access issues can be exacerbated by consolidation which has tended to eliminate smaller retailers or distributors who once served these communities. Moreover, smaller distributors and retailers are at a distinct disadvantage with pricing, given the fact that the largest supermarket buyers may be able to negotiate agreements with suppliers who use economies of scale to supply them at a particular price, but will experience significant diseconomies if the buyer abandons that supplier. Foer (2010) cautions about this “waterbed” effect where one buyer forces a discriminatory low price on a supplier which gains that buyer a competitive advantage, while at the same time the supplier tries to recoup some profit in selling to other buyers, thereby putting them at a disadvantage in the market place vis-à-vis buyer number one.

Ethical consideration must also be given to the environment. Investment in particular ways of growing and distributing food has been shaped by the consolidation that has happened in the food system. In order to better fit into the globally organized food chains, regions have specialized in production of certain crops or livestock (Lyson 2004), thereby eroding biodiversity and contributing to environmental problems such as nutrient runoff in water supplies, pesticide residues on

food and in water, and reduced soil fertility (McIntyre et al. 2008). Hendrickson (2015) argues that the organization of the dominant global food system reduces its social and ecological resilience. This compromises the ability of future generations to produce food for their societies.

As smaller farmers, processors, and retailers have been left out of the consolidated food system, the choices that communities can make about social and economic development options are limited by the structure of the food system and the allocation of labor, capital, and management in that system. Since the rise of the modern nation-state system, the availability, quantity, and quality of food have generally been considered a mandate of the government (Friedman and McMichael 1989). However, in the last few decades of globalization, food has moved from the public arena of the nation-state, into a private arena of decision-making that involves those within the dominant firms, including their management teams, boards of directors, and shareholders. When food moves from the public to the private realm, it becomes a privilege rather than a right, however unevenly that right has been claimed or fulfilled (Hendrickson et al. 2008a). With food a necessity for human life, this means consolidation of the food system affects the basic condition of what it is to be human. This certainly requires ethical thought and response.

Summary

Wendell Berry (1990) said that “Eating is an agricultural act.” While Berry was imploring consumers to understand their basic connection to agriculture and place, his statement explains the fundamental fact that agriculture is part of a complex food system spanning production, consumption, and waste. Moreover, food is a necessity and needed on a regular basis for all human beings, which makes the ethical implications of our food system structure and choices critical to our functioning as a society. In that sense, the food system is certainly part of our larger social, economic, and political systems and reflects and distills the ethical issues we experience within them.

The structure of the food industry has changed – becoming increasingly integrated and concentrated. Such change created or expanded a number of important ethical issues, most of which are derived from the fact that consolidation constrains the choices that farmers, consumers, and other food participants have.

Introduction

Discussions about the ethics of food and agriculture are replete with virtue and vice language. In agricultural ethics, it is often claimed that farming promotes good character traits – e.g., self-reliance, fortitude, and patriotism – and that virtues such as diligence, ecological sensitivity, and patience are central to good agricultural practice. In food ethics discussions, it is often claimed that character traits such as temperance and compassion are crucial to healthy and ethical consumption, whereas other character traits, such as gluttony and thoughtlessness, are inimical to them. This entry focuses on what makes character traits agricultural virtues and consumptive virtues, as well as on the role of virtue within agricultural and food ethics.

Section “[Character Traits, Virtue, and Virtue Theory](#)” discusses what virtues are and what makes a character trait a virtue. Sections “[Agricultural Virtues](#)” and “[Consumptive Virtues](#)” focus on the specification of agricultural virtues and consumptive virtues, respectively. Section “[Virtue and Right Action](#)” discusses the ways in which virtue promotes right action. Section “[Virtue Theoretical Ethics](#)” discusses

virtue-oriented accounts of right action. Section “[Agriculture and Virtue Education](#)” briefly discusses the view that farming is an effective means of moral education.

Character Traits, Virtue, and Virtue Theory

A *character trait* is a disposition to take certain types of considerations as reasons (or as motivational) for action or emotion under certain types of circumstances. Different people have different character traits if they are disposed to respond differently toward the same types of considerations. For example, a person who is consistently moved neither emotionally nor to action by the suffering of others (when she is in a position to help alleviate the suffering) is indifferent, whereas a person who is empathetic and tries to alleviate the suffering (when in an appropriate position to do so) is compassionate. The two people are disposed regarding the same thing – the *field* of both of the character traits is the suffering of others – however, they are differently disposed (Aristotle 1985). The dispositions that constitute character traits are not merely reactive; they are deliberative and conative as well. It is not just that a compassionate person feels and acts differently from an indifferent person; they understand and reason differently about the suffering of others. Character traits also have a perspectival dimension – they are relevant to how people “interpret” the world. For example, a selfish person is more likely to “see” a situation where there are scarce resources to be allocated as a problem of securing as much as possible for herself, while a just person will “see” it as a coordination or cooperation problem. A person who is concerned with the welfare of animals will “see” a concentrated animal feed operation as a system of suffering, whereas a person not so disposed might “see” a system of efficiency.

A *character virtue* (hereafter just “*virtue*”) is a well-justified character trait. It is a disposition to respond to considerations in the world in excellent ways. If the suffering of others is bad and one is indifferent to it (or aims to cause it), then one fails

to respond well to a morally salient fact about the world. Therefore, cruelty and insensitivity toward the suffering of others are vices, and compassion toward others is a virtue. To paraphrase Aristotle, a virtuous person is disposed to respond to the right thing, for the right reason, and in the right way while also having the right desires and feelings about it (Aristotle 1985). Specifying what counts as “right” for each of these is the central project within virtue theory.

There are several competing virtue theories, but the most prominent ones share this crucial feature: what constitutes right responsiveness is largely determined by the goods and values in the world (and the nature of those values), as well as by the relevant facts about the agent and her situation. According to eudemonistic virtue theorists, such as Aristotle, a virtue is a character trait that a person needs to flourish or to live well (Hursthouse 1999; Annas 1993). That is, flourishing is what is good or valuable, and the virtues are those character traits that are conducive to or constitutive of it. Other virtue theories are more pluralistic in that character traits are also assessed by their relationship to values other than agent flourishing – for example, how they contribute to the flourishing of other people, the welfare of nonhuman animals, the health of the environment, or the quality of social/civic systems (Swanton 2003; Sandler 2007; Treanor 2010). Take, again, the example of compassion toward the suffering of others. On a strictly eudemonistic approach, compassion toward the suffering of others is justified because the disposition is constitutive of (or conducive to) the agent’s living well – for example, with healthy interpersonal relationship and as a rational person (Hursthouse 1999; Foot 2001). On a pluralistic approach, it is also directly justified by the value of the flourishing of other people (Sandler 2007). (The justification is direct in the sense that it is not mediated by the relationship between the flourishing of others and the flourishing of the agent.) Moreover, because animal suffering is morally considerable (Singer 1975), the disposition to care about and try to reduce their suffering is a part of the virtue.

Because which character traits are virtues depends upon what things are good or valuable in the world, which character traits are agricultural and consumptive virtues is highly sensitive to the appropriate ends of agriculture and consumption. The next section discusses which character traits are agricultural virtues. The section after that discusses character traits associated with virtuous food preparation and consumption.

Agricultural Virtues

One way in which character has been thought to be related to agriculture is that there are certain character traits that dispose a person to farm well or to engage in good agricultural practices. Let us call these *agricultural virtues*. This section addresses what makes a character trait an agricultural virtue before turning to which character traits are agricultural virtues.

Some character traits – often called *enabling or cardinal virtues* – are conducive to doing almost anything well. Commonly recognized enabling virtues, in both secular and religious traditions, are traits such as courage, fortitude, thoughtfulness, and temperance. These character traits are considered cardinal virtues because they involve regulation of core emotional, cognitive, and conative responses. If a person lacks self-control, is easily discouraged, reasons poorly, and acts rashly, they are more likely to fail to accomplish their aims than is a person who is temperate, controlled, and deliberate. This is likely to be no different in farming than it is in law enforcement, education, or parenting. These character traits are agricultural virtues but only because they are human virtues more generally, and agriculture is a human activity.

Not all agricultural virtues are like this. For example, it is crucial to success in agricultural production that a person be ecologically sensitive, at least in a minimal sense. They must respond well to climatic and weather events; they must plan well regarding seasonal timing and changes; they must be attuned to the limits and possibilities of biological productivity. Being well disposed with respect to ecological dependencies,

vulnerabilities, and interactions more generally is not something that is necessary for good law enforcement or good dentistry. It is not a general virtue in the same way that is self-control. This does not, of course, imply that ecological sensitivity is a uniquely agricultural virtue: it is crucial to good conservation biology and water management practices as well, for example. But the field or domain of the virtue encompasses agricultural practice, and for that reason, it is properly an agricultural virtue. From this point on, “*agricultural virtue*” refers to virtues of this sort – i.e., non-cardinal virtues that are operative in agricultural practice (i.e., virtues whose field or sphere of application encompasses agricultural activity). Agricultural virtues are character traits that make for good farmers and are conducive to good agricultural practice.

Because agricultural virtues are character traits that are conducive to good agricultural practice, characterizing agricultural virtue is highly sensitive to what the appropriate ends or goals of agriculture are (which is dependent upon the values or goods at stake with agriculture). All agriculture has a common goal of the production of food or commodities. However, that is only a partial account of that at which any actual agricultural practice aims. In fact, there is wide divergence in views about what the aims of agriculture should be. On some views, the goal should be to maximize agricultural outputs or profits. On other views, the goal should be to produce food (or other agricultural commodities) compassionately and sustainably. On still other views, the goals of agriculture include maintaining cultural traditions and practices (Thompson 2010).

Different views on the ends or goals of agriculture support different accounts of which character traits are agricultural virtues. On the view that maximizing output should be the goal of agriculture practice, any element of the agricultural production system that is underutilized is detrimental to accomplishing the goal, and people ought to always be willing to incorporate novel organizational and technological methods for increasing yields. Therefore, if the end of agriculture is maximizing yields, character traits such as efficiency and innovativeness are agricultural

virtues. The idea that the end of agriculture is maximizing yields has been referred to as the industrial agricultural model (Thompson 2010). The impetus for it comes from the commodification of agriculture associated with the globalization of food systems, as well as from humanitarian concerns about how to feed a global population of over seven billion people.

The industrial agricultural model is not the only model for agriculture. On some views, both religious and secular, farmers are not only producers of a certain sort of commodity but also stewards of the land and of cultural traditions and communal practices (Shiva 2000; Berry 1997; Jackson 1985). On this view, the end of agriculture is not merely to produce food, but to do so in particular ways – i.e., ways that are consistent with the other values at stake. Agricultural practitioners must, therefore, be sensitive or responsive to a wider (or alternative) array of considerations. As a result, the character traits that constitute agricultural virtue can be quite different than they would be on the industrial model.

Consider, for example, the commitment to sustainability. There is a conception of sustainability embedded in the industrial agricultural model. However, it is a narrow and weak conception of sustainability. It is defined only in relation to agricultural production, and it can be accomplished even if the local resource base is diminished (e.g., topsoil and water), as long as external inputs can maintain productivity. Many people – both producers and consumers – advocate for a broader and stronger conception of sustainability. On this alternative view, sustainability has to do not only with maintaining or increasing levels of outputs but also with protecting resource bases and ecological systems beyond those directly related to agricultural productivity. Ecological sensitivity of this sort involves being responsive to considerations related to the biological richness of soil composition, greenhouse gas emissions from agriculture that contribute to global climate change, and agricultural runoff's impacts on water quality, for example. A person who is well disposed to promoting robustly sustainable agriculture will respond differently to the same

ecological considerations than will a person who is disposed only to maximizing yields. They will take different considerations as reasons for action, will have different affective responses, will adopt different goals, and will deliberate about things in different ways. So, again, which character traits are agricultural virtues is sensitive to what conception of sustainability ought to be adopted in agriculture.

Ecological sensitivity is not a unique virtue in this regard. The same holds with respect to compassion and animals. If the end of animal agriculture is maximizing output, then a disposition of indifference toward the suffering of the animals is justified except insofar as the suffering might affect yields. However, if the end of animal agriculture is to produce animal products with minimal suffering, then compassion ought to be extended to agricultural animals. Those who advocate for compassionate animal agriculture often do so on the grounds that it is necessary because nonhuman animals are morally considerable. That is, nonhuman animals have a sort of value or worth that goes beyond their mere instrumental value to people (Singer 1975). This illustrates, again, the way in which the appropriate ends of agriculture are dependent upon the values involved or at stake in agricultural activities. If only human well-being mattered, the dispositions regarding animals and ecological systems that constitute agricultural virtue would be quite different than if nonhuman animals and/or nature have (noninstrumental) value as well (Sandler 2007).

The possibility of cultural and communal ends to agricultural practices is also relevant to the specification of agricultural virtue. On many views, farming is a practice not only in food production but also in cultural stewardship. This stewardship can involve maintaining historical landscapes, traditional agricultural varieties, or traditional agricultural methods, for example. Moreover, agriculture-related practices, such as seed sharing, harvest festivals, and cooperative institutions, can be central to maintaining communal ties and cultural traditions. A concern frequently raised about industrial agriculture is that in the drive to promote efficiency, these cultural values and communal relationships are often undercut. As a result, commitment to cultural

and communal values or ends is often thought to favor more conservatism in agricultural virtue – for example, greater deliberateness in the evaluation and adoption of new technologies and prioritizing local independence and autonomy. It is for these reasons that those who emphasize community and cultural values in agriculture are often disposed against novel seed varieties patented by transnational corporations, as well as the displacement of local polycultures in favor of commodity monoculture (Shiva 2000; Berry 1997; Jackson 1985).

The foregoing is by no means an exhaustive account of the different views regarding agricultural virtue or the values and ends that are taken to be the basis for their specification. For example, many people believe that human rights, equality, and justice with respect to farm workers/employees and food availability/security need to inform agricultural virtue as well (Gottlieb and Joshi 2010). Nevertheless, it should be clear how and why the answer to the question “which character traits are agricultural virtues?” depends upon the answer to the question “what are the appropriate goals or ends of agriculture?” which in turn depends upon the answer to the question “what good and values are involved in agriculture?”

It should be noted that the answer to these questions need not be the same for all agricultural activities. Different types of agriculture, in different places and under different socioeconomic and ecological conditions, might, quite appropriately, have different ends. Some agricultural landscapes and practices are richer in cultural significance than are others; some are more central to communal relationships than are others; some have a greater capacity for contributing to food security than do others. This is not to claim that there are no character traits that are conducive to good agriculture generally. As discussed, cardinal virtues cut across all human activities, and there are elements of agricultural virtue that are appropriate to nearly anyone working to produce food. But these more general agricultural virtues are shaped by the particulars of agricultural forms, and their relative salience must be sensitive to socioeconomic and cultural context.

Consumptive Virtues

Just as there are character traits that are more conducive than others to good food *production*, there are character traits that are more conducive than others to good food *consumption* (which includes not only eating but also procurement and preparation). These character traits will hereafter be referred to as “*virtues of food consumption*” or just “*consumptive virtues*.”

As with all virtues, which character traits are consumptive virtues depends ultimately upon the appropriate ends, and so values and goods at stake, of the activity. Arguably, the most important end of food consumption is health. As a result, character traits that are conducive to healthful eating are, all other things being equal, more justified than are character traits that are conducive to eating behaviors that undermine health. It is for this reason that perhaps the most prominent consumptive virtue is temperance or self-control; and the most prominent vice is intemperance or gluttony. If we are not able to control or moderate our food consumption behaviors, then we are much more likely to eat (and drink) more than is healthy for us or to have a diet that does not meet our nutritional needs. (There are also many external factors that affect consumptive behaviors, such as availability and pricing of healthful foods, advertising and marketing, and nutrition education and information.) Moreover, having appropriate desires, emotions, practical reasoning, and perspectives on food is crucial to realizing many of the prominent social and aesthetic ends of food preparation and consumption. For these reasons, most food ethics would converge on the central importance of temperance and self-control as consumptive virtues.

Of course, food preparation and consumption are not only about nutrition and health. They are also central to culture and tradition, to daily rituals and practices, to social and familial interaction, to identity and connection to place, and to security and power, for example. Moreover, both preparation and consumption can be skilled practices and even art forms. Due to the myriad roles that food plays in human life and culture and the myriad ways it connects us to other people and to social

and ecological systems, there is an incredible diversity of virtues whose field encompasses at least some aspects of food preparation and consumption: aesthetic appreciation, gratitude, hospitableness, generosity, justice, compassion, patience, inventiveness, cultural sensitivity, openness, courage, courteousness, perseverance, inquisitiveness, efficiency, thriftiness, tolerance, reverence, and so on. It is not possible here to substantively discuss each of these character traits, but there are several virtues, in addition to temperance, that have become influential in the food ethics discourse in recent years. Some are the same as those that have become prominent (and are discussed above) within agricultural ethics: compassion toward nonhuman animals, ecological sensitivity regarding where our food comes from and how it is produced, thriftiness (i.e., avoiding profligacy) with respect to food waste, and justice with respect to treatment of food workers as well as food security/availability (Singer 1975; Gottlieb and Joshi 2010; Thompson 2010). Moreover, they are thought to be justified on the same sorts of grounds – for example, that nonhuman animals are directly morally considerable and that agricultural workers deserve full respect and rights.

Other character traits are more specific to food preparation and consumption. For example, there has been growing interest in developing simplicity and focality in the practice of food consumption, cultivating more adventurousness and aesthetic appreciation in the tasting of food, increasing awareness of the context or situatedness of food production, and developing greater self-sufficiency and autonomy with respect to food security (Petrini 2004; Pollan 2007; Gottlieb and Joshi 2010). These consumptive dispositions track food movements – e.g., slow foods, exotic foods, and local foods – since both the movements and the virtues are taken to be justified by the same values. Of course, these virtues, like the movements, are not uncontroversial. They are justified only to the extent that they track well the goods and values within their fields. Simplicity and focality, for example, are thought to promote healthy eating, reduce the ecological impacts associated with

one's diet, increase aesthetic and cultural appreciation of food, and promote beneficial social interactions around food. If those goals are well justified and the character traits are in fact conducive to accomplishing them, then they are justified as virtues to the extent that they do so.

As discussed above, the multidimensionality and prominence of food consumption in human life and culture give rise to a host of character traits being proposed as consumptive virtues. However, the fact that a character trait is regarded by some group of people to be a consumptive virtue does not make it a virtue. For any candidate consumptive virtue, the extent to which it is in fact a virtue depends upon both whether the ends at which it aims are appropriate and whether it is effective in realizing them. As with agricultural virtue, much work remains to be done on substantively specifying and evaluating which consumptive character traits are virtues and which are vices (Cafaro 2005; Wenz 2005; Sandler 2007).

Virtue and Right Action

The previous sections concerned what makes a character trait an agricultural virtue or a consumptive virtue and provided an overview of some of the character traits that are considered to be important agricultural or consumptive virtues. This section and the next one concern the relationship between virtue and right action. Characterizing this relationship is another central project within virtue ethics.

As discussed above, character traits dispose people to respond to certain considerations in particular ways. People with different character traits over the same field respond differently (practically, affectively, and conatively) to the same types of considerations. Thus, there is a tight relationship between character and action. People with different character traits over the same field will behave differently within that field because of their different character traits.

For example, consider again the two conceptions of ecological sensitivity discussed above – one that is oriented around sustaining agricultural productivity and the other that is concerned with

ecological conditions more generally. Agricultural activities cause, directly or indirectly, 15–20% of global greenhouse gas emissions. This information will be considered quite differently by a farmer, farm manager, or farm owner, depending upon which type of ecological sensitivity she possesses. The narrowly focused disposition, the one concerned with ecological considerations insofar as they impact productivity, will be concerned about how global climate change might affect agricultural outputs in the future. But she is not likely to see it as her responsibility to reduce emissions, particularly if doing so would require adopting practices or market approaches that would decrease yields or profits. In contrast, a person disposed to a broader conception of ecological sensitivity is much more likely to consider this information as relevant to how yields ought to be produced, and she is likely to be more open to methods and markets that are associated with fewer greenhouse gas emissions. Thus, one way in which agricultural virtue is related to agricultural practice is that it disposes people to respond to considerations in agricultural contexts differently. A compassionate poultry farmer concerned about animal welfare is going to respond differently to the impacts of battery cages on chickens than is a person who is not moved by the suffering of animals and does not consider it to be morally significant.

Moreover, virtues are not merely one among several possible character traits. They are well-justified character traits, dispositions that involve responding well to goods and values in the world. As a result, virtue does not just dispose its possessor to respond differently to situations, but to respond rightly. Virtue is conducive to right action. Agricultural virtue is conducive to acting rightly in agricultural situations. Consumptive virtue is conducive to acting rightly in consumptive situations. Agricultural animals are morally considerable in that their suffering is ethically relevant, and so it is not just that the indifferent poultry farmer acts differently from the compassionate poultry farmer with respect to the use of battery cages. The compassionate poultry farmer acts rightly, whereas the indifferent one acts

wrongly, and their different character traits explains (in part) why they do so.

In addition to disposing a person to perform right actions, virtue can help people to identify which actions are right. Sometimes people fail to do what is right, even when they know what the right thing to do is. Situation pressures can be strong and individual weakness (“weakness of the will”) can occur. However, at other times, people are insensitive to what matters in a situation, such that they simply are not able to see clearly what they ought to do. The indifferent poultry farmer does not see that battery cages are ethically problematic and then not care. They may not see them as problematic at all. They may not see what matters in the situation. This is an implication of the perspectival dimension of character traits. Thus, virtue not only disposes a person to do what they see as right; it also helps a person to see what is right.

Another way in which virtue is conducive to right action is through what is sometimes called the *integrating effect of virtue*. Often, right or virtuous activity is seen as involving significance sacrifice. For example, assume that it is right to aim for robustly ecologically sensitive agriculture. Doing so might require adopting more demanding or costly practices, or else might reduce yields. For these reasons, some people might not embrace it. From their perspective, it may look like something that just makes their work more difficult and less profitable. However, the costs associated with ecologically sensitive agriculture are likely to look quite different from the perspective of a person who already is ecologically sensitive. For her, the additional work is not just one more thing they have to do; it is a crucial component of accomplishing her goals and realizing her values. It may well be part of her self-conception or central to her worldview. Virtue integrates the agent’s values and perspectives with right action. This makes it more likely that she will do the right thing.

Yet another way that virtue is conducive to right action is that the sensitivity to values and context (i.e., wisdom) that is part of virtue is often crucial to determining the right thing to do in concrete situations. Many moral philosophers

have argued that it is implausible and unreasonable to expect that there is some finite set of rules or principles that can be applied by any moral agent in any situation to determine the proper course of action (Hursthouse 1999). If they are correct, then the wisdom and sensitivity that are part of virtue (including agricultural and consumptive virtue) are in some situations indispensable for identifying right action. For example, it might help agents to see whether they ought to maintain their dietary commitments, such as not eating meat, in the face of important social considerations, such as being a guest for whom a special nonvegetarian meal has been prepared.

Virtue Theoretical Ethics

The relationships between virtue and right action discussed in the previous section focused on the many ways in which agricultural and consumptive virtues dispose an agent to do the right thing. However, it left open the normative framework (e.g., consequentialist, communitarian, or deontological) that provides the account of what the right thing to do is. Some ethicists have suggested that virtue ethics or virtue-oriented ethics may provide an alternative theoretical framework to other approaches to specifying right action. On such a view – hereafter the *virtue theoretic view* – the virtues would be the primary evaluative concepts of the ethic, and right action would be explicated through them (Sandler 2007). That is, an action would be right not because it brings about good outcomes (consequentialism) or conforms with the moral law (deontology), but because it expresses or hits the target of virtue (Sandler 2007; Hursthouse 1999; Swanton 2003).

Virtue theoretic views suggest that decision making regarding what action or policy to pursue could be done by first identifying which virtues are operative and then determining what they would call for individually and overall. For example, in thinking about whether to include meat in one's diet, one would not look for the relevant moral law or run a utilitarian calculus. Instead, one would consider whether there is any meat available that is produced and procured in

compassionate, just, and ecologically sensitive ways (assuming those are the operative virtues). Because right action is explicated through the virtues on this view, providing substantive accounts of agricultural and consumptive virtues and vices is crucial to generating the normative resources for agricultural or food ethics.

Explicitly virtue theoretical approaches to agricultural and food ethics are not the dominant approaches. Rights-based and consequentialist approaches are more common. This is evident in the prominent framing of many food issues as between welfare economics justifications for maximizing efficiency in food production and distribution versus rights-based justifications for the protection of farmers, workers, and community autonomy. But virtue theoretic considerations often arise within the alternative approaches. This frequently occurs in the context of addressing longitudinal large-scale collective action problems. Many agricultural issues – such as those associated with pollution, industrial animal agriculture, and global food security – arise from the cumulative unintended effects of an enormous number of seemingly inconsequential decisions, and they can only be addressed by a very large number of people making seemingly inconsequential contributions to doing so. A person who chooses to adopt a low-emission diet has effectively no impact on global climate change, given the scale of emissions. Similarly, a person who chooses to adopt a non-factory farmed diet has effectively no impact on the industrial animal agricultural system. Given this problem of inconsequentialism (Sandler 2010; Jamieson 2007), ethicists very often appeal to the normative significance of character. For example, they will argue that it is a matter of avoiding complicity that a person should forego factory farmed meat if they think factory farming is ethically problematic, even if their doing so will have no discernible effect on the industrial animal agriculture system. Or they will argue that it is a matter of integrity that a person ought to unilaterally reduce their individual emissions, even though their doing so will have no discernible effect on global climate change. Thus, even when a normative theory is not explicitly virtue theoretic, very often virtue

theoretical considerations will be crucial to determining what constitutes right action.

Agriculture and Virtue Education

Thus far, the discussion has focused on what makes a character trait an agricultural or a consumptive virtue, as well as the relationship between agricultural and consumptive virtue and right action (i.e., the role of virtue within agricultural and food ethics). Another way that agriculture has been thought to be related to virtue is that agriculture is conducive to developing good character. That is, agriculture is an effective method of moral education in that it teaches such things as patience, diligence, inventiveness, self-reliance, cultural appreciation, simplicity, and other virtues.

Thomas Jefferson is among the Western thinkers most frequently cited in support of this view, owing to the following passages:

Those who labour in the earth are the chosen people of God, if ever he had a chosen people, in whose breasts he has made his peculiar deposit of substantial and genuine virtue. It is the focus in which he keeps alive that sacred fire, which otherwise might escape the face of the earth. Corruption of morals in the mass of cultivators is a phenomenon of which no age nor nation has furnished an example. (Jefferson 1984, p. 290.)

Cultivators of the earth are the most valuable citizens. They are the most vigorous, the most independent, the most virtuous, and they are tied to their country and wedded to its liberty and interests by the most lasting bonds. (Jefferson 1984, p. 818.)

These passages seem to suggest that there is a strong relationship between farming and good character (though it has been argued that when put in the context of the works in which they appear, their meaning is not so straightforward (Thompson 2000)). Similar sentiments can be found in the work and life of Henry David Thoreau (1951). However, not all historical thinkers have thought that farming was conducive to virtue. Aristotle thought that it was contrary to it:

The citizens must not lead the life of mechanics or tradesmen, for such a life is ignoble, and inimical to

virtue. Neither must they be farmers, since leisure is necessary both for the development of virtue and the performance of political duties. (Aristotle 1900)

Whether or not certain agricultural activities or forms of life are conducive to promoting certain virtues is largely an empirical question. To show that some agricultural form of life is conducive to virtue, one would need to demonstrate, using appropriate social science methodologies, that those who engage in those practices or form of life develop the character traits at issue at a comparatively high rate and that they do so as a result of their engaging in those practices or form of life. (Whether the character traits being studied are in fact virtues depends on the considerations discussed earlier.) Jefferson provides no such evidence, and neither does Aristotle. In fact, there has been very little empirical study of the effectiveness of agriculture as moral education. Until such time as that research is done, claims about the relationship between agriculture and virtue should be taken for what they are – interesting but unsubstantiated speculations (though, in some cases, perhaps plausible ones).

Summary

Considerations related to character play a crucial role in ethics. Substantive specifications of which character traits are virtues tell us what sorts of people we should be. Virtue is crucial to identifying and motivating right action. And virtue theoretical considerations often play a role in determining what we ought to do. In this entry each of these has been discussed as they relate to agricultural and food ethics. The many respects in which the character ethics of agriculture and food are underdeveloped have also been emphasized. Rigorous substantive specification of the character traits that constitute agricultural virtues and consumptive virtues is rare. The relationship between virtue and right action is often underappreciated. Claims about the relationship between agricultural practice and virtue education are often unsubstantiated. As a result, there remains a great deal of work to be done on virtue ethics within agricultural and food ethics.

War and Food

Bat-Ami Bar On
Department of Philosophy, Binghamton
University (SUNY), Binghamton, NY, USA

Introduction

This entry covers the place of food in its relation with war under four headings:

- (I) Logistics – It was not till the nineteenth century that the term logistics came to designate organized administrative military science. For a military or semi-military organization, just as more generally, part of what this science is about is the management of the production, storage, maintenance, and the flow of supplies between some point of origin and the intended consumers of the supplies. The administrative management of supplies is, among other things, the management of food and its social relations. In the case of war, the logistics of the food needed by military forces gets complicated by the strategic and tactical weaponization of food. The section on logistics attends to the military importance of solving logistical problems regarding food, some solutions, and some of the legal constraints placed on the solutions.
- (II) Strategy and Tactics – The Ancient Greek *strategos* was the military commander who planned a war or a campaign, and ever since then the term strategy has been used to refer to a plan that given a war's or a military campaign's goals offers the guidelines for the achievement of these goals. Strategy is concerned with the linkages among the many engagements that have specific objectives and are guided by tactics. In the case of food and war, strategy and tactics together determine forms of the weaponization of food. The section on strategy and logistics reviews some of the ways in which food has been weaponized either strategically or tactically.
- (III) Gender – Women and men have had and continue to have different roles in relation to both food and war. The gendering of women's and men's relations to food in war is entwined with logistics and necessarily gets complicated by the weaponization of food by strategy and tactics. Because during wartime nonmilitary women though not nonmilitary men get assigned specific tasks in relation to food, some restructuring their peacetime roles and others mobilizing these roles, it is important to discuss food in

war and its relation to gender. The section on gender analyzes some aspects of the triadic relation of gender-food-war.

- (IV) Normativity – The relation of war and food is normed culturally. It also continues to and should be framed by ethico-political normative constraints. Some of these constraints are customary, other legal, and many are still on the ethico-political normative horizon that is created by variously motivated wish lists that are developed and adjusted by, among others, academic ethicists and political theorists, religious leaders, and human rights activists who struggle against the weaponization of food. The section on normativity examines some of the primary ways in which the relation of food and war is and could be normed ethico-politically.

The entry as a whole is semi-casuistic in methodology, relying on cases, not all paradigmatic, to illustrate and develop its main points. Its bibliography is selective, not only because comprehensiveness seems impossible in the case of food in/and war but also because this is an underthematized topic.

Logistics

The Third Amendment to the US Constitution, which came into effect on December 15, 1791, states:

No Soldier shall, in time of peace be quartered in any house, without the consent of the Owner, nor in time of war, but in a manner to be prescribed by law.

The third amendment has never been explicated by the US Supreme Court and has surfaced constitutionally only in the discussions of privacy in *Griswold v. Connecticut* (1965) and that of limitations of executive power in *Youngstown Sheet & Tube Co. v. Sawyer* (1952). And yet, James Madison found it necessary to include it as one of his set of just 12 amendments to the constitution, all designed to create and safeguard specific civil and political freedoms. He did so because of colonists' objections to the English practice of involuntary billeting, which required colonists to provide English soldiers both lodging

and food, and he relied on the traditions of English law, which protected English citizens from involuntary billeting. Complaints against involuntary billeting were among those the colonists voiced in the *Declaration of Independence* and have previously brought to the attention of the King of England, appealing to him as his English subjects whose rights were violated. These rights were guaranteed legally by the 1679 Anti-Quartering Act of the English Parliament that applied to private homes and public structures in times of peace and war alike and the 1689 English Bill of Rights, which includes a right protecting its bearers against involuntary billeting (Fields and Hardy 1991).

Involuntary billeting solved an important logistical problem that was understood quite early in the history of organized war. Thus, one finds Thucydides noting in *The Peloponnesian War* (431 BCE) that the shortage of necessary food supplies forces armies to retreat and to enter into agreements with their enemies that they would have preferred to avoid. Caesar adds to these observations in *The Gallic Wars* (58–50 BCE), noting the Roman custom of expecting the hosting of Roman troops from allies and conquered peoples alike and pointing out that a smart strategist plans for shortages, as he did in 54 BCE, when realizing that he was unable to quarter all the Roman legions under his command together for the winter and so split them and the burdens of their hosting among multiple areas and Gallic tribes.

Armies have to be sheltered, clothed, and fed during war, and standing armies have to be sheltered, clothed, and fed during peacetime as well. In the *Wealth of Nations* (1776), Adam Smith suggests that, however unproductive their labor, the services of a standing army composed of disciplined specialists are needed by modernizing/modern countries such as England of his time. Smith expects the provisioning of a standing army to be financed through a state's treasury and argues for local requisitioning of shelter and food for troops that are stationed at a distance, as in the case of Britain's colonies, including the future United States. Billeting, whether voluntary or not, can be done through formal requisition but shelter and especially clothing and food can also

be acquired via pillage. Witnesses in England's colonies and elsewhere have claimed that sometimes it is quite impossible to distinguish between requisitioning and pillage.

Pillage was a common and accepted practice of war. Even after being outlawed, it has remained a common enough practice during violent conflict. The first legal document that prohibits versions of pillage and is still taken seriously legally as part of the documents that together elaborate current International Humanitarian Law (IHL) is the 1863 Lieber Code – General Order No. 100 – which was prepared by Francis Lieber and issued by President Abraham Lincoln during the American Civil War. By the time of the Civil War, the United States had enough experience with the organization and provision of specific food rations to its soldiers and both the Union and the Confederate armies ate similar foods, though over time the rations of Confederate soldiers grew smaller. In addition, due to extensive logistical problems and bad planning, the Confederate army did not have enough food supplies in depots or available for requisitioning and its soldiers turned to foraging (Ballard 2004).

Strategy and Tactics

In his 1812 campaign against Russia, Napoleon Bonaparte discovered that an army in need of foraging can be starved into defeat. As part of their defensive strategy against the *Grand Armée*, the Russians instituted a scorched-earth policy so ruthless that they left nothing of value for the advancing Napoleonic forces, which were used to living off the land. The Russians learned from the Portuguese who 2 years earlier, in 1810, successfully used slash-and-burn tactics against Napoleon's army. Napoleon did not learn from his failure in Portugal, a fact that surprised Carl von Clausewitz. Clausewitz believed that Napoleon was a strategic genius who, unfortunately, was disposed to taking some unnecessary reckless risks. Among his comments about the 1812 campaign is this one: "it is undeniable that the lack of care over supplies was responsible for the unprecedented wastage of Napoleon's army on the advance and for its wholly calamitous retreat" (1984/1832, p. 339).

Clausewitz centered military marches as a means to decisive battles and, therefore, thought of food and other necessary supplies under logistics, though he was aware that the need to feed soldiers has been used tactically and strategically in defensive wars, as in Portugal and Russia, and in offensive wars as well. One of the most successful offensive uses of an army's need (and the needs of the civilians on whose behalf it was fighting) for all kinds of supplies occurred almost 50 years after the failed Napoleonic campaign in Russia, when the Union relied on a tightening blockade to win its war against the Confederacy in the American Civil War. While prohibiting pillage and requiring humane treatment of civilians and enemy soldiers alike, the Lieber Code did not prohibit blockades. The Union's blockade strategy, known as the "Anaconda Plan," was developed by the General-in-Chief of the US Army Winfield Scott. The actual Union strategy put into action modified Scott's original plan to permit more military engagements than Scott wanted to pursue. Even in its modified version, the blockade, which basically starved the South, was key to the Union's success (Smith 2011).

In current warfare, blockades have become less important strategically since militaries have become better at logistics and soldiers in combat or at outposts that are removed from their bases are supplied with Meals Ready to Eat (MRE) that are well calibrated not only nutritionally but also in order to appeal to many tastes and meet diverse religious restrictions. But the blockade has remained a tool of war. Thus, for example, in 1982, the United Kingdom blockaded the Falkland Islands after Argentina occupied them during the Falkland War and Israel has blockaded Gaza since 2007. In addition, blockades have been used by the United Nation's Security Council, NATO, and similar coalitions.

Blockades are lawful under international law but only when governed by specific rules. Among the legal constraints on blockades is section 54 of *Protocol I of the Geneva Conventions*, which bans strategies and tactics that involve the destruction of food supplies or/and the means to grow food in an area of conflict. Section 54 states:

Starvation of civilians as a method of warfare is prohibited. It is prohibited to attack, destroy, remove, or render useless objects indispensable to the survival of the civilian population, such as food-stuffs, agricultural areas for the production of food-stuffs, crops, livestock, drinking water installations and supplies, and irrigation works, for the specific purpose of denying them for their sustenance value to the civilian population or to the adverse Party, whatever the motive, whether in order to starve out civilians, to cause them to move away, or for any other motive.

Gender

International law's protection of civilians against starvation, whether in the case of blockades or the use of scorched-earth policies or slash-and-burn tactics, may have been agreed to because of sexism, which in times of war and in warlike violent conflicts is expressed in gendered treatments of soldiers and civilians. Indeed, even the distinction between "soldiers" and "civilians" tends to be gendered (Carpenter 2006). One can find a representation of the gendering of war already in the *Iliad* and *Odyssey* (800 BCE) with their reference to a war fought by men over access to one woman – Helen of Troy – while another woman, Penelope, waits patiently and faithfully for her husband, though she too is the subject of an intense competition for access.

Both Helen and Penelope were confined to and by Greek domesticity but they were not expected, unlike women in World War I and World War II England and the United States, for example, to reconceive the home as a "front" and the feeding of their families as a "contribution to the war effort." War had to become total war in its twentieth-century version and involve the mobilization of the whole population in order to reshape daily life and deploy women to accomplish much of the reshaping. The totalizing of war in England during World War I brought with it the organization of the Land Army, which started its activities in 1915. Its members worked as field laborers growing food mostly on land confiscated by the British Government under the Defence of the Realm Act (DORA) of 1914.

By 1917, about 260,000 women worked as field laborers in England and the United States instituted its own Women's Land Army, both of

which were remobilized in World War II (Carpenter 2003; Kramer 2008). Wartime women field laborers, like their much better known counterparts, wartime women factory workers, filled positions otherwise held by men. At home, in the domestic private sphere, as well as in in-between spaces of public food production, such as victory gardens, or food preparation and service, such as in charity dinners, women continued to perform along the lines dictated by their gender roles, though in a manner reconfigured through state interventions.

In both world wars, among the serious supply problems was food, resulting in inflationary prices, which exasperated class divisions and increased social instability. Rationing, less successful in World War I than in World War II, was not enough, especially since it was accompanied by an informal market in rationed goods and rationing cards that undermined some of the intentions for rationing. States, therefore, turned to women in their domestic roles to solve the complex set of food shortages and related social problems they faced. They addressed women as wartime homemakers and told them that their "real and most important battlefield was the kitchen. There women could – and should – fight the war and prove their patriotism by cooking and serving the right kind of foods in the right kind of ways" (Bentley 1998, p. 31).

For mainstream United States, due to British influences that can be traced back to colonial times, the "right foods" and the "right way" defined dinner as consisting of a large portion of a high-status food, such as meat, served together with two complementary foods, such as bread and vegetables. During World War II, the US government successfully changed the mainstream understanding of the "right foods" and the "right way" by introducing the forerunner of the 2011 US Department of Agriculture "plate" and its predecessor, the 1992 "pyramid" – the "basic seven." An interesting and quite significant difference between the "basic seven" and the 1956 simplified version of "basic four" is that meat features in the fifth place among the "basic seven" and in the first place among the "basic four." Indeed, "meat" is the first word one reads on the "basic four" list,

calling attention to both meat's recovery as a high-status food and the United States' ability to sustain its prosperity while the Cold War was going on.

The "basic seven" offered a list of the "right foods" but just eating the foods on the list did not exhaust the meaning of eating the "right way." The "basic seven" had to be eaten in the "right quantities," as defined by gender, age, and even occupation differentiated caloric needs. In addition, their "right production" was expected to be quite economical. Home food production in the form of gardening and canning, though labor intensive and in many cases an additional burden for women, many of whom now also worked outside the home, defined the "right ways to produce food," with canning adding the benefit of saving foods for seasons during which gardening is impractical.

Normativity

"Right" is a normative term. In the United States, in the case of the relation of gender, food, and war during World War II, the set of criteria used to distinguish between the "right" and "wrong" foods, the "right" and "wrong" quantities for their consumption, and the "right" and "wrong" modes of their production were also used to distinguish between the "right" and "wrong" ways to perform gender, thereby norming gender. As wartime criteria they had another use – norming patriotism by distinguishing "patriots" from those who failed their patriotic obligations, a failure that was usually attributed to the moral character flaw of *akrasia* or weak-will (Veit 2007).

Most of the norms that appear to seamlessly connect gender, patriotism, and food are cultural. Some are legal. Exchanges on the informal market in rationed goods and rationing cards during World War II were prohibited and punishable by law, adding a clear negative incentive to the shaping of conduct by new cultural norms. In international society, law is among the most important instruments norming engagements in war. International law prohibits all but for defensive wars, thereby prohibiting wars whose goal is the acquisition of food by force, though it is among the more usual kind of resource wars that are increasingly caused by the growing needs that are

coproduced by capitalist globalization and climate change. The alternative to war is a more equitable division of access to the means of food production and food itself, among the goals of global justice, a realizable though at present utopian normative ideal because thus far it has not mobilized enough institutional support.

The prohibition on food-as-resource wars is not only legal but also ethico-political and falls under the *jus ad bellum* branch of the just war theoretical framework, which is concerned with the normative justification of and thus normative constraints on engagements in war. Like current international law, current *jus ad bellum* principles permit only defensive wars. If one could construe the denial of food or access to food as a form of aggression, then such a denial could serve as a basis for a claim to have a just cause that justifies a serious consideration of an attempt to secure food by violent means. But, a just cause is only a necessary and not a sufficient condition for an engagement in war, and in the case of food, its force as a condition is mitigated by the existence of international aid. Recent warnings by the Food and Agriculture Organization of the United Nations, however, do point out that food insecurity is unacceptably high, especially in countries that experience protracted violent crisis that compromises the supply of food, food production, and access to food. Food insecurity, then, becomes a cause of and exacerbates further violence.

Food, even if primarily a resource that is required to address basic human needs, is rarely merely a simple means. Food is a significant part of any culture and at least some foods can count as a "cultural property." As such they ought to be protected by the 1954 *Convention for the Protection of Cultural Property in the Event of Armed Conflict*. But, the convention, which mentions, books, artworks, and archaeological sites, does not mention any foods. And yet, the French, for example, consider their wines to be a national cultural treasure. The Nazi German elite concurred with this judgment. As a result, starting in June 1940, the Nazis transferred French wines to Germany by direct looting (as in the stealing of 80,000 bottles from the cellars of Paris's La Tour d'Argent), Nazi takeovers of famous wine

production houses (such as Moët and Chandon in the Champagne region, which began business in 1743 and was known for supplying Europe's royalty, aristocracy, and its wealthy families), or the coercive reduction of the price of all the wines the Nazis purchased through the monopolization of demand, the offer of under market value, and the punishment of noncooperation with fines, prison, as well as deportation to labor and death camps (Kladstrup and Kladstrup 2001).

The protection of food-as-cultural-property falls both outside existing international law and outside current just war theory. Just war theory is basically minimalist in its construction of human needs. To the extent that food, its production, and access to it are protected within the theory, it is by the macro- and micro-versions of the principle of proportionality. Both versions of the proportionality principle set normative constraints on the harms and damages of war and require engaging in cost-benefit analyses that weigh harms and damages against specified goods. The principle of macro-proportionality is a *jus ad bellum* principle that requires a prediction about the overall harms and damages and overall good that are expected from a war. The principle of micro-proportionality is a *jus in bello* principle that requires predictions regarding the harms and damages and goods that are expected from specific acts of violence undertaken in a war. Because a consequentialist calculus is used in the application of both versions of the principles of proportionality, they can protect food only to a limited extent. The logic of such a calculus necessarily permits some harms and damages in general and will permit some harms and damages that are caused by the weaponization of food. This is why under certain conditions, attacking food supplies, fields, food factories, roads that are used to transport food, and the like, may all be ethico-politically permissible.

The *jus in bello* principle of discrimination, which requires that distinctions be drawn between combatants and noncombatants, can be used to protect food for noncombatants. The principle identifies who is and who is not liable to intentional attack. Its various interpretations assume that noncombatants are not liable to intentional

attack. One could argue that an intentional attack on food is an intentional attack on the people who need the food that is attacked. If noncombatants are not liable to attack, then the food of noncombatants ought to be protected (Thomas 2005).

The *jus post bellum* branch of just war theory, which is concerned with postwar justice, can contribute to the protection of food, if and only if one allows considerations of the postwar goals of a just war to play a decisive role in the case of both *jus ad bellum* and *jus in bello*. This is Immanuel Kant's approach in *Perpetual Peace* (1795). According to Kant, peace is the only goal of a just war that has intrinsic value and so constrains even the engagement in defensive wars, let alone actions during a war, demanding that both not undermine the possibility of postwar peace. Kant's argument could be used to protect food at least insofar as its destruction might undermine peace. This argument is, however, weak and a different Kantian idea, that of human dignity and the normative demand to not undermine it, can be mobilized to create much stronger protections of food. Such an argument might actually be launched not only to protect food-as-resource but also food-as-cultural-property, though in order to argue that food must be protected as cultural property, one will have to mobilize communitarian assumptions about the importance of group membership to personal identity and therefore to one's sense of one's own dignity.

A Kantian sort of argument could be advanced when human rights are mobilized to protect food. But most human rights arguments for the protection of food are much weaker than a Kantian argument that centers human dignity because they treat food merely as satisfying a basic need. While human rights arguments might be weaker in an ideal sense, in practice they are the stronger ones because a basic right to food in the case of armed conflict is protected by international law (Pejc 2001). Under the 1998 *Rome Statute* that established the International Criminal Court, intentionally starving civilian populations is a crime of war. And according to a complex body of international law, the doctrine of double effect, which is used to excuse some unintended consequences, cannot be easily invoked in the case of

food. The law requires that if food or access to food is destroyed, relief agencies be allowed to distribute the food that people need. From the perspective of concern with human dignity, the problem of transforming an independent population into one dependent on relief agencies for the fulfillment of its basic needs is extensive. This has been recognized by the United Nations which has started to mix its normative terms in order to be able to act on Jean Ziegler's claim (n.d.):

The right to food is a human right. It protects the right of all human beings to live in dignity, free from hunger, food insecurity and malnutrition. The right to food is not about charity, but about ensuring that all people have the capacity to feed themselves in dignity.

Waste and Food

Elizabeth V. Spelman
Philosophy, Smith College, Northampton,
MA, USA

Synonyms

Feasting; Food loss; Food waste; Garbage; Garden of Eden; John Locke

Introduction

The necessity of food for human survival grounds our prudential and our ethical interest in its not going to waste. Given our undeniable need for the nutrition food provides, it seems both irrational and irresponsible to fail to make good use of it before it perishes.

However, such certainty about our need for food hardly makes our relation to it, or to the wasting of it, clear and uncomplicated. As feasts, for example, remind us, the significance of food in our lives is not limited to the satisfaction of basic biological need. And when food is not being used simply or only to still hunger, questions about whether it is being wasted do not have obvious answers. Moreover, "waste" has several meanings. The seventeenth-century English philosopher John Locke, for example, assumed as a matter of course that both letting food spoil and failing to cultivate the earth in order to grow food constitute waste. The fact that the original inhabitants of the "waste" lands in the Americas to whom Locke was referring might well have disagreed with his latter claim reveals yet another important feature of the concept of waste: its deployment in normative judgments.

The many uses of food, the several senses of “waste,” and the battle over norms that the invocation of “waste” often reflects have to be acknowledged in any discussion of what constitutes food waste. As urgent are current concerns about food waste in the global context of famine, starvation, and food insecurity, these matters also should be seen in light of humanity’s long history of reflection on the significance of food and the meanings of “waste.” Before focusing, then, on contemporary sources of food waste, we shall describe some moments in that rich and complex history: John Milton’s proposal, in his account of the Book of Genesis, that food spoilage emerged only when humanity fell from a state of innocence; the prevention of food waste as the foundation for property rights, in John Locke’s *Second Treatise of Government*; and the importance of food waste in feasts.

Rotting Apples and the Fall from Innocence

Forth reaching to the fruit, she plucked, she ate.
(Milton 1991, Book IX, 781)

Many of the accounts humans have given of their relation to food suggest that it is hard for us to countenance the possibility that the world into which we are born would not be adequate for our sustenance as long as we think and behave in ways appropriate to our place in that world. One such influential account is John Milton’s expansive treatment of the story of Adam and Eve in the Garden of Eden in *Paradise Lost* (Milton 1991).

On Milton’s rendering of *Genesis*, the Paradise in which God placed Adam and Eve was a land of plenty. Food was abundant and delicious. Neither scarcity nor anxious fear of it threatened. While the Garden needed some tending, the trees some lopping and pruning, the labor involved was not particularly arduous, just taxing enough to whet the appetite.

But if such abundance ruled out scarcity, did it at the same time create waste? Wasn’t there more than enough food for Adam and Eve? If so, was not such excess wasteful?

In *Paradise Lost*, the very idea of waste in the Garden does not arise until the serpent successfully tempts Eve to eat the fruit of the forbidden tree. The reason given for the lack of concern about waste is not, as one might reasonably hypothesize, that any food unneeded and uneaten by Adam and Eve was devoured by animals or turned into compost. The Garden was not waste-free on account of some fine economy of nature according to which one species’ leavings readily became another species’ takings. Rather, it is as if God’s fruits have a kind of built-in preservative:

For many are the trees of God that grow
In Paradise, and various, yet unknown
To us, in *such abundance lies our choice*,
As leaves a greater store of fruit untouched,
Still hanging incorruptible, till men
Grow up to their provision, and more hands
Help to disburden nature of her birth.
(Milton 1991, Book IX, 618–624 [emphasis added])

There is glorious excess, and yet nothing spoils. Or at least so it was until Eve allowed herself to be beguiled by the serpent. Addressing the tree of knowledge, she declares that it makes no sense to let “thy fair fruit. . . hang, as to no end created”. Only after emboldened by the serpent, that “fittest imp of fraud”, did it occur to her that surely the tree with its fruit was created to be used and surely its use is to be eaten. It would be wasteful not to treat it accordingly. Eve will “ease” its “fertile burden” (Milton 1991, Book IX, 798–799; Book IX, 89; Book IX, 801).

Eve, and then Adam, the story goes, disobeyed God’s explicit instruction not to eat of the tree of knowledge. In *Paradise Lost*, there is no waste before these acts of disobedience (Gee 2010). Eve and Adam’s failure brings about material conditions in which formerly “incorruptible” fruit now suffers decay and goes to waste unused. This change in nature is accompanied by the emergence of human claims to know waste when they see it: surely unused fruit has a purpose that goes unfulfilled unless it is eaten. But such judgment is beyond the ken and outside the jurisdiction of humanity. Humans are not in a position to know why things were created, what purpose they might serve, and their thinking they know the

proper use of that apple is instrumental to their disobedience.

Milton's gloss on *Genesis* posits that Eve and Adam's disobedience consisted not merely in choosing to eat from the forbidden tree but in assuming the authority to judge what is waste and what is not. At the same time, God does not disagree with the human assessment that Adam and Eve and their progeny were condemned to live in what in comparison with Paradise is a wasteland. The "verdure" is "spoiled", the cattle die "of rot and murrain [infectious disease]" (Milton 1991, Book XI, 832; Book XII, 179).

John Milton invites us to think of Paradise – the mythical home for the Old Testament's first man and woman – as a place in which food is not only not scarce but magnificently bounteous. And yet in all that excess there is no waste: fruit does not spoil however long it is on the tree. But once Adam and Eve thought that there was an unrealized potential that should not go to waste – what might be gained from eating of the tree of knowledge – the world became a wasteland, and the threat of scarcity entered into human life.

Food Waste and Property Rights

In Milton's rendition of *Genesis*, food waste has a striking role in the history of the relation between humanity and God. In John Locke's *Second Treatise of Government* (Locke 1980), food waste is crucial to the foundation of property rights.

The natural world in which Locke locates humanity is God-given but also marked by signs of our expulsion from Paradise. God gave us this world with all its rich floral and faunal resources and blessed us with the capacity to reason, which allows us "to make use of [the world] to the best advantage of life, and convenience" (Locke 1980, p. 18). But this world is, after all, postlapsarian: we have to labor much harder and longer than did the still-innocent Adam and Eve, and earth's apples are no longer "incorruptible." Since this world was given to us "in common" (Locke 1980, p. 18), we all have a right to its resources. But there are both conditions for and limits on the exercise of this right. Your labor entitles you to a

portion of what is in given in common. Go forth and pluck, gather, hunt, and fish. But not to your heart's content. For there are limits to what a person can make his or hers: God gave us all this plenty for us to "enjoy," that is, to "make use of to any advantage of life before it spoils" (Locke 1980, p. 20). "Nothing was made by God for man to spoil or destroy" (Locke 1980, p. 21).

It is not just the edible items humans come across in nature that can be of use to them in obtaining sustenance. There is also the land. And indeed by the time Locke was writing the *Second Treatise*, toward the end of the seventeenth century, the "chief matter of property" of English denizens was "now not the fruits of the earth, and the beasts that subsist on it, but *the earth itself*" (Locke 1980, p. 21). Man and woman are no less entitled, indeed no less bound, to make use of the land than they are to gather what nature offers independently of their digging into the soil. "*As much land* as a man tills, plants, improves, cultivates, and can use the product of, so much is his property" (Locke 1980, p. 21, emphasis in the original). But there are limits here, too, on appropriating common land: as long as one leaves "as much" and "as good" land as existed before the appropriation (Locke 1980, p. 21), it's as if one has taken "nothing at all" (Locke 1980, p. 21).

Cultivating land properly improves its value. Appropriators actually "increase the common stock of mankind" (Locke 1980, p. 23): a single acre of cultivated land could easily produce many times the "provisions" of "an acre of land of an equal richness lying waste in common" (Locke 1980, p. 23). If there is waste in allowing food to rot, meat to putrefy, so too there is waste when land that might be cultivated goes unfurrowed and unplanted. Indeed "we shall find the benefit of it amount to little more than nothing" (Locke 1980, p. 26). Think about bread: it is only because of the tremendous labor that has gone into the cultivation of land, the invention of tools, and the distribution of the final product that it is available to us as bread. "...nature and the earth furnished only the almost worthless materials" (Locke 1980, p. 27). They may be "materials of plenty" (Locke 1980, p. 25), but their potential is not realized apart from human labor. Our capacity to toil is thus

implicitly a greater gift to us from God than what God provides independently of our labor.

In Locke's post-Edenic world, God has provided bounteously for humanity, but the waste of food is an ever-present possibility that humans must attend to sedulously. The occurrence of waste in nature – food waste in particular – is clear evidence that a person has mismanaged and misused God's plenty. You are welcome to pluck apples from a tree and to kill a deer you come across in the woods in order to sustain your life. But if you allow the apples to spoil or let the animal flesh putrefy, you have abused your right to the riches God has provided. You also are not only welcome but commanded by God "to subdue the earth, i.e., improve it for the benefit of life" (Locke 1980, p. 21), not leave it in a state of waste, i.e., uncultivated.

There are then according to Locke at least two senses in which food waste is to be understood: (1) as the loss, the draining away, of the use value of existing foodstuffs (e.g., rotten apples, stinking carcasses) and (2) as the untapped, unrealized potential of land to be cultivated in order to create foodstuffs, something Locke espied across the Atlantic:

for I ask, whether in the wild woods and uncultivated waste of *America*, left to nature, without any improvement, tillage or husbandry, a thousand acres yield the needy and wretched inhabitants as many conveniences of life, as ten acres of equally fertile land do in *Devonshire*, where they are well cultivated? (Locke 1980, p. 24; emphasis in the original)

Locke here adopts the very view about waste that was Eve's undoing: Eve wondered why God would create an apple that would go unused; Locke takes it as a given that surely God wants us to see land that might be cultivated as lying in waste should it not be tilled. Of what value can such land be if it is not used to create food? "...land that is left wholly to nature, that hath no improvement of pasturage, tillage, or planting, is called, as indeed it is, *waste*" (Locke 1980, p. 26).

This understanding of food waste is central to a Lockean-inspired view according to which settlers from elsewhere had the right, in fact the duty, to take possession of uncultivated lands in America.

According to Locke, the only or in any event the far superior use of land is to cultivate it. He implicitly rules out the possibility that any other use of the land, any other value it could have, is irrelevant – for example, the Miltonic idea that God's glory might be revealed in bounteous excess, or the notion that hunting and gathering are adequate and respectful ways of sustaining life.

So in the case of both Milton and Locke, we can see that because (a) food has many uses beyond its role in sustaining human life and (b) "waste" is a normative term, there are bound to be differences over whether a particular use of food is wasteful, along with struggles over whose view ought to prevail. In Milton, the idea is broached that humans fail to honor the splendor, power, and authority of God when they insist that they know what is useful for humans and what is not; in Locke, there is the claim that it's precisely when humans fail to mine the world for what is useful to humanity that they go against God's will and that others have the right, in fact the obligation, to go forth and cultivate. In *Paradise Lost*, we are said to not be not good judges of what constitutes waste; in *The Second Treatise*, we are instructed that the capacity for reason that God gave humans enables us, indeed requires us, to judge what is wasteful and what is not.

Feasts

Food waste, then, has been of concern not only for humanitarians, environmentalists, or public health experts. Influential figures in western intellectual life have made the topic of food waste central to attempts to understand the relation between humans and the gods they believe in, as well as to lay out the grounds on which property rights are to be established. In the meantime, humanity, in all its motley glory and across time and culture, has given the wasting of food a central role in celebrating life, in glaring back defiantly into the face of scarcity, and in establishing or maintaining social relations.

Feasts have a prominent place in human history. Coming in great variety, they can be religious, irreligious, or nonreligious in intent; they

may be designed by and for royalty or peasantry; sometimes they function to confirm existing social hierarchies, other times to temporarily dislodge them (or do the former by doing the latter); they might sanctify order or celebrate disorder. But among the basic elements of feasts, whatever their mood and aim, are food and drink. And, if at all possible, the victuals are to be as plentiful and delicious as possible, even at what may be extraordinary expense to individual or community creating them (Dietler 2001, pp. 82, 96). The specialness of the food marks the specialness of the occasion: feasts typically are offered to show honor, respect, or gratitude for some person or deity or to underscore the importance of an event such as a birth, a death, a wedding, and a victory. The provision and intake of more than enough food and drink is called for.

Feasts thus are likely to involve waste in a number of ways: the very idea of a feast tends to suggest that there will be not only enough but a prodigious amount for all the participants. While the excess might be given to animals or humans not among the feasters (e.g., a fourteenth-century English court might include an “almoner” among whose tasks was to direct leftovers from the feast to the poor (Strong 2003, p. 91)), it might also be left to rot. (The post-Thanksgiving behavior of many North Americans has centuries-old antecedents). Having enough to waste is part of the point of the feast. That is among the reasons why a Luo family in west Kenya, for example, might exhaust its supply of food, knowing that some of it will quickly become garbage, rather than keep themselves from going through a period of near starvation (Dietler 2001, p. 96), or why an about-to-be-married couple in the USA put themselves in hock for a splendid and heavily garbage-producing feast for family and friends.

Though the food in such feasts is going to waste in the sense of spoiling instead of being consumed, it is not going to waste at all in another sense, for the provision of the food and the attendant waste are crucial to whatever social or political work the feast performs. Thorstein Veblen (Veblen 2009) reminded us vividly of what feast-makers and students of the *potlatch* have always known: conspicuously and wastefully consuming

goods – including food – can be a fine means of creating or maintaining your status.

At the same time, perhaps we should be careful about assuming that what appears to be wasteful behavior – such as the excessive and lavish provision of food at a potlatch feast – must be serving *some* kind of useful function. Recently, Samuel Martínez, invoking George Bataille, has raised doubts about the appropriateness of “explaining all behavior in terms of marginal utility or social functions”: after all, isn’t “the potlatch’s main source of fascination, the symbolic banishment of necessity and creation of a momentary illusion of inexhaustible wealth” (Martínez 2010, p. 612)? Is what seems to be wasteful excess of food something to be rued or an invitation to explore the significance and reach of what Martínez suggests is nonrational but not irrational behavior?

One can take Martínez’s suggestion under advisement without having to treat all instances of food waste as exuberant celebrations of non-utilitarian expenditure. But perhaps sometimes our attempts to interpret and redeem behavior that appears wasteful, by proposing an end or use in terms of which the behavior is not wasteful, stand in the way of understanding such behavior. Maybe sometimes wasting food is just wasting food, perhaps an expression of defiance in a world far distant from the Paradise of Adam and Eve.

Food Waste: Current Assessments

The United Nations Food and Agricultural Organization estimates that one third of the amount of food intended for human consumption ends up being wasted or lost (FAO Media Centre 2011). Not surprisingly, the effects of such waste are not experienced uniformly. A portrait of food distribution across the globe today strongly suggests something like feasts for some and famine or food insecurity for others. Food waste and food loss are important factors in the creation and maintenance of such asymmetry. Tristram Stuart among others has argued that the food waste produced by rich countries such as the USA and Britain could feed almost all those in the world not receiving

adequate nourishment (Stuart 2009, p. xvi; FAO Media Centre 2011) and that a reduction in food surplus in wealthy countries, in conjunction with a reduction of postharvest losses in relatively poor countries, would substantially save the supply of food around the globe (Stuart 2009, p. 193). Moreover, given the multiple resources needed to produce food, its waste and loss also threaten the sustainability of land and water and have implications for climate change.

Consumers are by no means the only or the greatest wasters of food. No doubt in places such as the USA and England, palpable evidence of great quantities of food gone to waste surely is visible in household refrigerators and the municipal landfills to which the trash is hauled, as well as on the plates of restaurant patrons. But tracking down records of how much food is wasted by farmers, food corporations, restaurants, caterers, and supermarkets is not easy (Stuart 2009, pp. xxi, 11). Unlike the growing number of conscientious citizens keeping blogs about how much food waste and other trash they create and dispose of, these major creators of food waste are reluctant to compile data about their waste, and on the whole their governments have not been eager to require them to do so.

Food is a heavily marketed commodity, and supermarkets in particular are continuously trying to create and also reflect market standards for the desirability and acceptability of food. Just because farmers or fishers produce something edible and nutritious doesn't mean it will be attractive to those who supply food markets. If markets insist that people won't buy forked carrots, slightly bruised apples, or knobby cucumbers, then tough luck for farmers, who by some estimates can lose up to a third of a year's harvest (Stuart 2009, p. 102). Farmers also may overproduce in order to insure that they match what they have contracted to supply. All such excess food might be plowed back into the land, but to deny it is going to waste on such grounds is to ignore the enormous cost of land, water, labor, and capital involved in producing it to begin with.

Once the food that survives the standards gets on market shelves, there is no guarantee that it won't end up in the dumpsters behind the store.

Among the many factors conspiring to produce such waste are the mostly meaningless "sell by," "use by," "best until" tags; a presumed customer desire to see shelves full of the freshest and prettiest stuff; fear that selling slightly "old" stuff, or even making sure it goes to survival centers, would inspire customers to wait for the bargains or go to the centers.

Attitudes toward food waste can differ rather starkly across cultures. Unlike the majority Han Chinese, for whom hospitality includes making sure to offer more food than can possibly be eaten by guests or patrons, Muslim Uighurs in China take pride in preventing waste in the preparation and distribution of food (Stuart 2009, pp. 199–201). A culture's attitudes can vary over time: countries such as the USA and Britain certainly have shown in wartime that they can produce anti-food-waste campaigns and practices (Stuart 2009, pp. 234ff.). But developed countries seem to have evolved a food supply system that in effect requires waste, and they tolerate, indeed seem to encourage, its acceptance, or at least are quite ready and willing to obscure its scope.

There is, however, growing recognition of the extent of food waste and promises of earnest effort to diminish it at all points along the production and consumption lines. For example, the European Commission has published a multi-language 10-step program for household waste reduction (European Commission 2012). The European Parliament, building on statistics provided by the FAO, has issued a report that among other things

Considers that, in order to reduce food waste as much as possible, it is necessary to involve all participants in the food supply chain and to target the various causes of waste sector by sector; calls on the Commission, therefore, to make an analysis of the whole food chain in order to identify in which food sectors food waste is occurring most, and which solutions can be used to prevent food waste. (European Parliament 2011).

Summary

This necessarily brief survey of reflections on the moral significance of food waste is but a small,

preliminary, and provincial taste of the topic, an amuse-bouche. According to John Milton, the very inconceivability of food waste was part of the plenteousness in the Garden of Eden. We would not know of such waste had it not been for Adam and Eve's fateful disobedience. John Locke's notion of the wrongness of food waste was central to attempts to justify European settlers' appropriation of land in the Americas. Feasts, in all their cultural and historical variety, are particularly vivid reminders of the function of food waste in sustaining social relations.

Questions about the bounteousness of the earth, the capacity or willingness of humans to make wise and fair use of it, and the meaning of feasts in the face of famine have not disappeared. Among the starkest and most immediate of the ethical concerns raised by food waste in the context of the early twenty-first-century global economy is the relation between the massive waste of food and widespread but preventable famine, food insecurity, and starvation.

Water, Food, and Agriculture

Keith Dromm

Louisiana Scholars' College, Northwestern State University, Natchitoches, LA, USA

Introduction

Access to clean freshwater is becoming increasingly difficult for many people around the globe. The problem of water scarcity will require both local and global remedies and the implementation of permanent, long-term solutions. Ethical issues arise at the levels of both the crisis and its solutions. They also do not result only from the problem of water scarcity. All water use has impacts on humans and the environment that require ethical consideration. The first section of this entry summarizes the water crisis and reviews generally the ethical issues it entails. The second section briefly discusses several proposed solutions and their ethical implications. The third section examines the idea that there is a human right to water. The fourth and final section considers different water management paradigms and their approach to the ethical issues of water use.

The Water Crisis

Water is a truly renewable resource. The water humans consume today is the same water that was consumed by their biological ancestors over billions of years. Where the water has been

located, and in what forms, has changed over these years, and it will continue to change, possibly in ways that are detrimental to human and other forms of life. Presently, freshwater makes up only 2.5% of the world's water. Almost 70% of that water is frozen in glaciers; 30% of it is located underground in aquifers (groundwater); this leaves a little more than 1% in permafrost, lakes, rivers, biological organisms, and the atmosphere.

Despite these percentages, the total amount of water available for direct consumption or use in agriculture and industry is abundant, but it is not equally distributed around the globe. Around two-thirds of the world's population live in places that receive just one-fourth of the annual precipitation, around four billion people (Pennington and Cech 2010, p. 2). Pressure on water sources is increasing due to population and economic growth, climate change, and poor management of water resources and services.

What is an impending water crisis for most is a present reality for many others. Approximately 1.1 billion people do not have access to clean drinking water. The water they can access requires great expenditures of time and energy in order to retrieve. This task usually falls upon women and children, and it can occupy up to 4 h of their day. The result is that adult women are prevented from engaging in more productive labor and children lose those hours that could have been spent in school (or simply enjoying childhood). Both factors are forestalling economic development in water-poor regions. It is estimated that in sub-Saharan Africa, 5% of GDP, or \$28.4 billion, is lost annually because of inadequate water and sanitation services. People living in poverty in water-poor regions – most of whom only survive on less than \$2 a day – bear most of these costs (United Nations Development Programme 2006, p. 6).

Water scarcity is a function of both quantity and quality. Water pollutants – naturally occurring and anthropogenic – include microbial pathogens, sediment, chemical toxic substances, heavy metals, and excess nutrients like nitrogen and phosphorous. Some of these pollutants can directly affect sources of drinking water, for example, by entering groundwater. Others can have deleterious effects on the environment,

some of which can also result in decreased water quality, for example, by damaging wetlands that act as natural filtration systems for water. In water-poor regions, water scarcity is typically exacerbated by inadequate sanitation, which can introduce microbial and other pollutants into water sources. 2.6 billion people worldwide do not have access to basic sanitation (UNESCO 2012, p. 65). Approximately 80% of the world's wastewater flows untreated into rivers, lakes, and other sources of drinking water (with higher percentages in developing countries). The world's rapidly growing cities are major point-source polluters. For example, Jakarta, a city of nine million, treats less than 3% of its wastewater (UNESCO 2012, p. 66). An estimated three million people – mostly children – die annually in developing countries from waterborne illnesses (United Nations Environment Programme 2007, p. 13). Half of all the people in these countries at any time are suffering from illnesses caused by deficiencies in sanitation and water quality (United Nations Development Programme 2006, p. 6).

Water for domestic use, such as for drinking, makes up only a small portion of water use. Worldwide, 70% of water use is for agriculture (it is closer to 80% in developing countries, with industry and agriculture consuming more equal amounts of water in developed nations, and domestic use still the smaller percentage) (United Nations Development Programme 2006, p. 138). Increased agricultural and industrial uses of water are making the highest demands on water resources. Economic growth, and not only a growing world population, is responsible for the increasing demand on water resources. Whereas over the last hundred years the population has increased fourfold, the demand for water has increased sevenfold (United Nations Development Programme 2006, p. 137). An improving worldwide economy is resulting in a greater demand for water-intensive food products, such as meat and dairy (e.g., it takes 3500 L of water to produce 1 kg of rice, but it takes 15,000 L of water to produce 1 kg of beef). Industrial demands for water also increase with an improving economy, including energy production, which relies heavily on water. Agriculture and industry are also major

contributors to water-source pollution, which can impact water quality.

Some of these increasing water demands caused by economic growth are met by transfers in “virtual water,” which are products that consume water at the place from which they are exported. For example, developed and BRIC (Brazil, Russia, India, and China) nations are buying farmland in regions like Africa to produce agricultural products for import. While this practice is relieving water demands in the importer nation, it is increasing pressure in the water-poor regions which tend to have less efficient management and weaker laws regarding water use (UNESCO 2012, p. 50).

Climate change is also having an effect on water resources. Decreased precipitation in certain regions and increased evaporation due to global warming are contributing to the depletion of surface and groundwater. While the melting of glaciers will increase river flows in the short term, glaciers act as water reservoirs, and their disappearance will mean the loss of major water resources (which might occur in some places, such as South America). The acidification of ocean and rainwater, another effect of climate change, is having deleterious effects on biological productivity, including agriculture.

Misuse and waste of water resources is another contributing factor to water scarcity. Water-poor regions tend to be economically poor, which inhibits the development of efficient water infrastructures for domestic use. Developed nations are confronting problems with deteriorating water infrastructures. Agricultural use also widely suffers from inefficiencies, such as evaporation and leaks. Poor sanitation, as it has been noted already, can decrease water quality (and thus the quantity of clean water) by polluting freshwater. In developing nations, only 10% of wastewater is treated before being discharged back into the environment, and only 10% of treatment plants function efficiently (United Nations Environment Programme 2007, p. 132). Excessive groundwater pumping is resulting in not only depletions of water resources but land subsidence, intrusion of saltwater into aquifers, and increased costs from the need for deeper drilling.

All of these pressures on water resources are predicted to increase as the world population grows and the effects of climate change become more severe. Water use is expected to increase 50% by 2025 in developing nations and by 18% in developed nations (United Nations Environment Programme 2007, p. 121). In many parts of the world, water use already exceeds the replenishment of resources, e.g., in the High Plains of North America and the Indo-Gangetic Plain in South Asia. Climate change will further slow replenishment in these and other parts of the world. It is expected that by 2050, 1.8 billion people will be suffering from “absolute water scarcity,” and two-thirds “will be under conditions of water stress” (United Nations Environment Programme 2007, p. 129). Many people in the world are aware of the water crisis, including those currently living with it; others, especially those in water-rich nations, are only slowly learning of it.

The ethical issues of water use arise at both the levels of the crisis and its solutions. The crisis generates urgent moral imperatives for action, including increasing awareness of it and the need to devote attention to its solutions. Another related ethical issue concerns who are responsible for alleviating the crisis. For example, do developed nations (which tend to be water rich) bear responsibility, and how much, for alleviating the crisis in developing nations? The solutions to the crisis reflect various ethical presumptions ranging from the ownership of water and whether it should be treated as an economic or social good to the environmental and cultural impact of water solutions. Solutions to the crisis occur at both the individual and collective level. Individuals in water-stressed regions have obligations to be conservative in their water use. This obligation can also arise in water-rich regions depending on the use and source of water. For example, an abundance of groundwater does not relieve its users of an obligation to conserve water, especially if this water is being consumed at a rate greater than its replenishment; users need to be conscious of the availability of water for future generations. Their use of water also makes demands on water infrastructure and creates pollution, impacts which are independent of water quantity. In desperately water-poor regions, individuals do not have enough water to be conservative about. In

water-poor urban areas served by water utilities, there can be a tendency to hoard and otherwise manipulate the water infrastructure in order to meet daily needs. At the collective level, efficient and ethical management of water uses (to be discussed later) are an essential part (and source) of solutions to the water crisis. Water management is essential for avoiding the classic and notorious “tragedy of the commons” problem; without the management of a public good like water, users will tend to deplete or otherwise destroy that good. But the distinction between individual and collective responsibility is not a sharp one. Individuals make decisions that affect collective action; as voters and/or consumers, they influence both public and private uses of water. Management solutions can assume either a restrictive or inclusive scope. The former would focus solely on satisfying water needs, whether short term or long term, and the latter a broader consideration of the social and environmental impacts of water use. But the distinction between restrictive and inclusive scope is also becoming increasingly more difficult to draw. For example, different water-use solutions, such as the construction of dams, have environmental impacts that can affect the quantity and quality of water.

Solutions

The solutions to the water crisis include applications of specific technologies to increase the supply of freshwater, as well as more general strategies for alleviating the demand on water resources. The ethical implications of these solutions concern their ability to address both the water crisis in equitable ways and externalities, like the effects of these solutions on the environment.

Desalination involves taking saltwater and converting it into freshwater. It can provide a major source of water for coastal regions. However, the process is energy intensive and uses expensive technology, putting it out of reach for many countries. Also, a by-product of many desalination methods, such as reverse osmosis, is a high-saline brine. When this is discharged back into the ocean, the salinity of the surrounding water is increased, and this can damage the marine ecosystem. Water

intake from the oceans can also damage marine life. Technologies are being developed to mitigate these environmental impacts.

Effluent reuse is similar to desalination in that it takes a source of nonpotable water and converts it for drinking and other uses. Many municipalities direct wastewater that has undergone some treatment for agricultural and industrial use, as well as municipal uses like the watering of parks. The technology exists to make wastewater clean enough for drinking, but there has been resistance by potential users. The objections are mostly aesthetic. The idea of drinking what was recently flushed down a toilet or a drain is unappealing to many. These anxieties can be countered by pointing out, as it was at the top of this entry, that any water that humans drink has passed through numerous biological organisms, including themselves, and that the treated wastewater can be cleaner than water from other sources. Wastewater treatment also produces a by-product that has been directed to agricultural use, but some worry about pollutants in this waste entering the food chain, such as the residue of pharmaceuticals consumed by humans.

These solutions involve finding new sources of water. Other, less feasible, solutions have been proposed. Some have suggested towing polar icebergs to water-starved regions. Also, there are many places around the globe that enjoy a surplus of freshwater. Some have proposed shipping this water long distance in ocean tankers, but the current cost to do so makes this unfeasible.

Another set of solutions to the water crisis involves improving the management of existing resources to ensure their reliability and longevity. Different water management theories will be discussed in a later section. Important proposals related to the management of water resources are the *privatization* of water resources and services and the creation of *water markets*. Their advocacy is motivated by both free-market ideology and conservation concerns (Glennon 2005; Anderson and Leal 2010; Gleick et al. 2002). Many believe that setting a price on water will reduce demand and increase efficiency of water services; if water consumers have to pay for water, they will use it more wisely and less of it. In the United States, for

example, most consumers pay only for the delivery of water, not the water itself. If they were to pay for the water, as well as allowed to transfer their rights to it, then a water market would develop that would set a “true” price for water and run efficiently without the need for much, if any, government regulation. Chile, which has had a market-based water policy since 1974, is often cited as a model of such an approach, but whether it has been successful is contentious (Anderson and Leal 2010, pp. 95–96; Bauer 2004). Some have argued that markets cannot capture all the costs of water. For example, they do not by themselves consider third-party effects of water transfers, such as those on the members of community where the water transfer originates (Sax 2010). Also, markets do not consider the effects of transfers on future users.

An ethical and political problem that confronts management solutions to the water crisis is the fact that many watersheds cross national boundaries. Rivers that cross through several countries are the clearest example of this. The Rio Grande passes through the United States and Mexico; the Nile passes through ten countries. Disputes over the use of such watersheds are a perennial problem of water use and can only be alleviated through better cross-nation cooperation. The Nile Basin Initiative is one example, although it has not solved all of the disagreements of the participating countries. In addition to cooperation, cross-boundary watersheds also highlight obligations that states owe one another. For example, a country that dams a river must consider the consequences to downstream users of the river, even those in another country.

Water as a Human Right

In order to encourage the implementation of solutions to the water crisis, and to influence the types of solutions that are pursued, many have called for the recognition of a human right to water. In 2002, the UN Committee on Economic, Social and Cultural Rights recognized an implicit right to water in Articles 11 and 12 of the International

Covenant on Economic Social and Cultural Rights (General Comment 15). This was followed in 2010 with a resolution by the UN General Assembly that recognized a human right to water and sanitation (UNGA Res. 64/292). A small number of states identify an explicit right to water in their constitutions, such as the Republic of South Africa.

A human right to water would ensure that the basic water needs of individuals are met. One widely endorsed estimate has this to be 20 L of water daily for each adult individual. This is well below the average daily use of those in the United States (400 L) and Europe (200 L). Even so, it is above the estimated daily use of 5 L by individuals in water-poor regions. Even the states in these regions that are actively trying to improve their water situation lack both the funds to improve the water infrastructure and the water sources needed to fulfill this basic needs minimum. On the subject of costs, the advocates of a human right to water are quick to point out that it does not entail that water should be free. It should be affordable. It should also be easily accessible and of a sufficient quality, but those who can should pay for the water and its delivery.

Besides the practical problem of fulfilling a human right to water, the human right to water suffers from some conceptual problems. For example, it is not clear who is the addressee of such a right, that is, who bears the corresponding duties and responsibilities of a right to water. The UN resolutions and comments, as well as the state constitutions that recognize a right to water, make governments the addressee. This presupposes that the government has a monopoly over water sources and services, an imperative to assume such a monopoly, or the power in some other form to ensure that the basic water needs of citizens are met. Again, there are both practical and conceptual problems with this presupposition. One possible way to resolve both sorts of problems is to deny that all rights entail correlative duties held by individuals or governments (Sampford 2009). But this would broaden the category of human rights to include what resemble aspirations or goals of a community. Rights, however, are more than this. They are

enforceable, and their recognition can be demanded. Both acts imply some target or addressee of the right.

One way to meet at least the conceptual demands of a human right to water is to recognize water as a common good not subject to anyone's appropriation, like air. Water and air are in many respects alike. They both move or flow, and they are renewable. However, air is ubiquitous above the surface of the earth, and water is not. Also, there are no consumptive uses of air. That is, the air humans use for breathing as well as such things as firing coal plants is immediately returned to the atmosphere (although, in the case of the latter and many industrial uses, with pollutants added). Some important water uses are consumptive. The legal regimes that have arisen around water use reflect this and are not all compatible with the idea of water as a common good.

The *riparian doctrine*, which dates back to the Justinian Code of 533 CE, holds that landowners have a right to the water in a stream or river that adjoins their land. The right to this water is not transferable, that is, it cannot be transferred apart from transfer of the land. The water removed needs to be put to reasonable use and returned in as close to the same condition to its source. The riparian doctrine only works well in humid regions; in arid regions, water must be diverted across the land to be of use. The *doctrine of prior appropriation* was developed to accommodate these uses. It was applied in the western United States during the gold-mining boom (mining makes extensive use of water) and was likely derived from English common law and the *acequia* system of Hispanic law. It grants a right to water to whomever diverts the water for beneficial use. They do not need to own land adjacent to the source, and priority is given to those who first make use of the water over those who come later. The *public trust doctrine*, which is another one to have origins in the Justinian Code, contends that air, running water, and the sea are held in common by all humans. The state retains title to them and is obligated to regulate them for the benefit of all its citizens. The public trust could be relied upon by states to fulfill a human right to water, but it conflicts with doctrines like prior

appropriation, and it does not cover all water sources. The use of groundwater has been subject to less legal regulation. Some doctrines have mandated certain limits on pumping, such as the *reasonable use rule*; others have endorsed mostly unlimited pumping, such as the *rule of capture* (Pennington and Cech 2010, p. 378ff). Only the public trust doctrine is consistent with a human right to water, but not sufficient. Making such a right consistent with existing legal doctrine – or overriding those doctrines – poses both legal and ethical challenges.

Water Management

Whether water is a common good or property, wise management is necessary to ensure the sustainability and accessibility of water resources. A laissez-faire approach to water use is no longer a possible approach to water use in a time of increasing scarcity. Over the last few decades, several different management paradigms have been proposed and adopted. These paradigms consist of tenets of water management that are intended to promote the wise and efficient use of water.

In the 1980s, *integrated water resources management* (IWRM) emerged and eventually became the dominant paradigm for water management. It arose in response to the recognition that the management of water must be coordinated with that of other resources, their various uses, and the entirety of stakeholders. It advocates an interdisciplinary and multi-institutional approach to the management of water resources and services. IWRM has been endorsed by numerous world organizations, including the United Nations Environment Programme, the United Nations Development Programme, the World Bank, and the Global Water Partnership (GWP). The GWP has provided the most widely cited definition of IWRM as:

a process which promotes the coordinated development and management of water, land and related resources, in order to maximize the resultant economic and social welfare in an equitable manner without compromising the sustainability of vital ecosystems. (Global Water Partnership 2000, p. 22)

This definition has been criticized for its vagueness (Biswas 2008). Nevertheless, several states have attempted implementing IWRM, with varying degrees of success (Petit and Baron 2009).

The ideas behind IWRM have a long history (stretching at least as far back as the early twentieth century), as do some of its competitors, such as *adaptive management*. This approach to management has roots in the writings of Aldo Leopold, in particular the “Land Ethic” section of *A Sand County Almanac* (1949). It also reflects the insight that water and other resources are unstable and undergo unpredictable variations. Large-scale water management projects such as for irrigation or flood control assume stability and make humans more susceptible to harm from unanticipated ecological change (Brown and Schmidt 2010, p. 9). Adaptive management is a strategy for ensuring the *resilience* of ecological systems. It involves a pragmatic approach to water management that emphasizes experimentalism and social learning (Norton 2010). *Ecohydrosolidarity* can be considered a species of adaptive management, although distinguished from both it and IWRM by a greater emphasis on human rights and social justice. First articulated by Malin Falkenmark and advocated by organizations like the Stockholm International Water Institute, with which she is affiliated, ecohydrosolidarity combines insights from both ecology and hydrology to, for example, draw attention to the functions of both *blue water* (liquid water flow) and *green water* (e.g., soil moisture). Traditional water management has focused on the former, even though it is only one-third of water resources, and green water is involved in plant production, which supplies food and other critical needs for humans. An understanding of, and attention to, the interaction between blue and green water is essential for effective water management (Falkenmark and Folke 2010).

All management paradigms make ethical pre-suppositions, and their implementations have ethical implications. Some explicitly acknowledge the ethics, such as ecohydrosolidarity, while others, in particular some advocates and practitioners of IWRM, try to disguise them behind a value-neutral, objective approach to the problem

of water scarcity. However, merely the identification of a problem reflects an ethical judgment. Also, as it was discussed above, all solutions to the water crisis have ethical implications, and the choice of solutions reflect ethical judgments.

Summary

The water crisis is affecting a large and increasing percentage of the world’s population. Population and economic growth, climate change, and the misuse and poor management of water resources are placing pressures on existing water resources. Solutions to the water crisis include finding new sources of water, such as through desalinization and effluent reuse, and improving the management of water resources and services, including privatization and the creation of water markets. All of these solutions have ethical implications. The recognition of a human right to water is another type of response to the water crisis that seeks to influence governments and international organizations to act to alleviate the crisis. The notion of a human right to water suffers from some practical and conceptual problems, and it is incompatible with much of existing water law. Several management paradigms have been advocated as another way to respond to water scarcity and other problems associated with water use. They vary insofar as they incorporate the ethical dimensions of water use and scarcity, among other ways.

Introduction

Women are key actors in rural development as they make essential contributions to the agriculture sector and have a major role in food security and nutrition in developing countries. However, gender inequality persists worldwide, depriving women and girls of their basic rights and opportunities as well as means to profit from agriculture such as information, resources, access to services, land, finance, and technology that are more easily accessible to men. Moreover, rural women are more likely to be food insecure than men and more likely to suffer from nutritional deficiencies

especially during adolescent growth, menstruations, pregnancy, and breastfeeding. Additionally, in many cultures they eat the least and last within the household even deprioritizing their own nutrition in times of food of scarcity. Hence, young mother's not having sufficient nutritional knowledge and not being able to take care of themselves and their children has been widely proved to be a key factor in the perpetuation of the cycle of poverty through the next generations (IFAD et al. 2009). Achieving gender equality and the empowerment of women and girls will therefore require vigorous efforts, including legal frameworks, to counter deeply rooted gender-based discrimination that often results from patriarchal attitudes and related social norms (UN 2017).

The discourse on women's empowerment is divided between those who consider it as a means to achieve other outcomes focusing mostly on efficiency arguments on one side and on the other side those who consider empowerment as a basic human right, which is an end in itself. For example, FAO Policy on Gender Equality stresses the instrumental role of empowerment:

(The gender gap) reduces women's productivity and diminishes their contributions to the agriculture sector, and not only affect their well-being and that of their families, especially in terms of food and nutrition security, but it also imposes a high cost on the economy through productivity losses [...] closing the gap in agriculture would produce significant gains for society by increasing agricultural productivity, reducing poverty and hunger and promoting economic growth. (FAO 2013)

Nonetheless, besides efficiency arguments, there are also practical and heuristic reasons for focusing on rural women's empowerment. Alkire and colleagues showed that there is a clear association between women's empowerment in agriculture (which is the main economic sector in rural areas) and empowerment in other domains as greater decision-making and greater autonomy about minor household expenditures, serious health problems, protection from violence, religious faith, their own daily tasks, and the use of family planning (Alkire et al. 2013). This association suggests that raising women's empowerment in agriculture could affect numerous other dimensions of empowerment.

The 2030 agenda aims to “leave no one behind” so that a special focus on particularly vulnerable social groups, as rural women, is necessary. Furthermore, in order to meet Sustainable Development Goal 5: “Achieve gender equality and empower all women and girls”, UN have made noteworthy progress in advancing gender equality and women’s empowerment in rural contexts, in particular through a wide action plan (UN-SWAP) and landmark agreements such as the Beijing Declaration and Platform for Action and the Convention on the Elimination of All Forms of Discrimination against Women (CEDAW), which Article 14 specifically addresses the issue of rural women.

In the global development scene, numerous NGOs and international organizations work on rural women’s issues, namely, FAO, IFAD, and WFP that are part of a specific interagency task force on rural women. Their knowledge on the matter as well as guidance to implement programs and policies targeting rural women has been assembled in the *Gender in Agriculture Sourcebook* based on the expertise of a great number of gender and rural development specialists, which together with FAO flagship publication *The State of Food and Agriculture 2010–2011, Women in Agriculture: Closing the Gender Gap for Development*, represents the conceptual and empirical basis to the present discourse on women’s place in rural development.

This entry will provide a grasp of such matters describing the major trends and challenges in rural women’s empowerment and gender equality. However, rural women should be always considered as very heterogeneous group differing by age, wealth, social status, education, marital status and system, stage in their life cycle, race, ethnicity, sexual orientation, on- and off-farm livelihoods, and location (Bishop 2017). Moreover, since gender relation is complex and highly context specific, the following paragraphs will inevitably picture a general view, insisting however on the necessity of a deep understanding of local contexts and individual differences for any further analysis or intervention.

Feminization of Agriculture

Among economically active women in developing countries, 79% spend their working hours producing food through agriculture, and women workforce participation in agriculture is over 60% in several regions of sub-Saharan Africa and South Asia. Moreover, a trend of “feminization of agriculture” in different regions emerges from various sources. This process is mainly due to men outmigration, to the globalization of agri-food systems, as well as to conflicts and pandemic diseases, which a recent report from the World Bank links to changes in rural economies and in women’s roles in agriculture.

As men move out of agriculture, in many developing countries, women stay or move out in a significantly slower manner increasing the number of female-led households among the “rural left-behind women.” Therefore, women become increasingly involved in remunerated agricultural work contributing to their own empowerment in the household and in the community. However, this situation may exacerbate gender gaps as women still perform the bulk of unpaid household work while men, migrating to cities, access more lucrative jobs (Slavchevska et al. 2016).

Gender Inequalities in Agriculture

Due to culture-specific gender norms surrounding the division of productive and reproductive labor between sexes, men usually bear greater authority over decisions relating to agricultural production, as well as more control over productive resources and services. Consequently, women are often excluded from opportunities to participate in and benefit from rural entrepreneurship even when they are key producers of household subsistence crops (IFAD et al. 2009).

Androcentric social norms often relegate women within the household to take care of their families, while men, on the other hand, are expected to provide all of the household income. As a consequence girls are taken out of school at an early age to assist their mothers or to be married and therefore undereducated and burdened with

childbearing and parental responsibilities at a very young age. These practices lead to reduced freedom of movement for women and gender imbalances in household and community decision-making limiting women's access to and control over livelihood resources, services, and markets (IFAD et al. 2009).

In fact, the 2017 High-Level Political Forum (HLPF) Thematic Review of SDG 5 highlighted the fact that women spend 19% of their time on unpaid care work, which is over twice of the time men dedicate to such chores. Moreover, rural women and girls experience a triple work burden in the productive, reproductive, and social spheres, and unlike men, their work is mostly unpaid and unrecognized. As a result, they work longer and have less time to engage in income-generating activities, to attend school and take care of themselves (HLPF 2017).

Land and Other Agricultural Assets

Gender equality in productive resource ownership is a key dimension of gender equality in rural areas. Furthermore, there are strong gender differences in the access, use, and control over agricultural assets throughout the world, nationally, locally, and within the household (IFAD et al. 2009). Even in the cases where women are documented as owners, this does not mean they will have full ownership rights over these assets because of gender-biased legislations, intra-household power relations, informal institutions, and other culture-specific practices affecting women's full access to property rights (Odura 2017).

Assets such as land, equipment, housing, agricultural labor, extension knowledge services, financial assets, and livestock confer social status and recognition to their owners; additionally they can be used to directly generate income or as collaterals to access financial services. Asset ownerships by women influence their livelihood strategies increasing their self-esteem, their bargaining power, their position in the household, their productivity, and their well-being (Meinzen-Dick et al. 2014).

FAO estimated that if women had the same access to productive resources as men, they

could increase yields by 20–30%, leading 100–150 million people out of hunger in the world (FAO 2011). Moreover, the control over assets, leading to important development outcomes such as food security, child nutrition, education, and women's well-being, has been found as a more stable pathway out of poverty rather than income or consumption-oriented measures (Meinzen-Dick et al. 2014).

Land is a key asset to secure livelihoods and reduce poverty in rural areas. However, as land tenure systems are inherently gender biased, rural women are unlikely to be landowners; when they do own the land, the sizes and qualities of their plots are significantly inferior than men's. Moreover, women have to struggle with both statutory rights and customary norms and through all the channels that allow them to access the land: the market, governmental or nongovernmental initiatives, and more commonly marriage or inheritance (Lastarria-Cornhiel et al. 2014). Guatemalan sociologist Ana Patricia Castillo Huertas stresses the fact that land tenure initiative always selects beneficiaries by marital status so that in any case women are included in a subordinate way, still depending ultimately on the presence of a man in their household to claim their land rights (Castillo Huertas 2015).

Credit and Markets

Rural finance is central to development; it has been enhanced all around the world by NGOs and international organizations to benefit the poor through small loans, remittance services, savings, and micro-insurances. However, such important services can accentuate gender inequalities as rural women throughout the world have less access to credit, savings, and insurance services than men of equivalent socioeconomic conditions. Moreover, in contexts where sociocultural norms restrict their mobility, in particular their possibilities to leave the household by themselves and engage in professional relations with other men and their opportunities to attend trainings, receive formal education, access financial institution, and reach markets to sell their products are compromised. Additionally to these limitations to their access to information and inputs, cultural

norms often limit their confidence in engaging in such activities and limit their control over income. Finally, rural women are discriminated by the financial institutions as they consider them as small and unexperienced clients and generally lack tailored programs addressing rural women specific needs (IFAD et al. 2009, Fletschner and Kenney 2014).

Climate Change

The Intergovernmental Panel on Climate Change (IPCC) established that the effects of climate change that are leading to an increasing ecological degradation, affecting poor and vulnerable people, and in particular rural women, are heightening gender inequalities, as existing structural disparities that women face in many rural societies are further exacerbated by such menaces on their lives and livelihoods (IPCC 2013). Namely, women are more vulnerable to climate hazard than men, because they rely more on biomass (such as wood, agricultural crops, wastes, and forest resources) for their energy and food security needs and livelihoods. Moreover, as for their agricultural production and natural resource harvesting, they have fewer assets, entitlements, and access to information and services than men; they will have higher exposure to climate risks (IFAD et al. 2009).

Some examples of these gender-based vulnerabilities are the following: women, boys, and girls have been estimated to be 14 times more likely than men to die during natural disasters mainly because of their reduced access to warning information and cultural barriers for women to learn to swim (e.g., 70% of fatalities from 2004 Asian tsunami and 96% of 2014 Solomon Islands floods were women and children); most households in sub-Saharan Africa and Southeast Asia rely on firewood for cooking which is usually collected by girls; in some sub-Saharan African countries, fetching water may use up to 85% of a woman's daily energy intake, and in times of drought women can spend up to 8 h a day in search of water (UNDP 2013).

However, as women are culturally more tied to natural resources, they have an important role in conservation efforts, such as seed saving as well

as growing and preserving side crops and neglected and underutilized species. These species are essential to integrate the household diet with nutrients and are potential gene sources in case of collapse of commercially viable varieties; they are also important to reduce vulnerabilities to climate shocks and improve the household food security. As the agriculture "feminizes" and men migrate away from the rural areas, female farmers come to play increasingly important roles in maintaining knowledge about different plant varieties and deciding which crops to plant (IFAD et al. 2009).

Because of their increased vulnerability to climate change and their key role in natural resources management, rural women's unique experiences and valuable skills are crucial in all phases of the disaster risk management cycle. Moreover, achieving gender equality and women's empowerment is an essential condition to successfully adapting to climate change impacts (UNDP 2013). This is why women are key actors in the major climate-related development approach in rural areas, the climate-smart agriculture (CSA) which aims to increase agricultural productivity and incomes in a sustainable way, help individuals and communities adapt and build resilience to climate change, introduce laborsaving technologies, and reduce greenhouse gas emissions, where appropriate (IFAD et al. 2015).

Women's Empowerment in Agriculture

The lack of data and accurate measures is often a barrier for gender policies within development organization. Moreover, not having a precise data baseline seriously undermines assessments of progress and key target points, often also leading to intra-agency tensions due to skepticism over non-data-oriented policies. The issue when it comes to women's empowerment, especially in rural areas, is that it can be measured in several ways, but each has its own limitations because of the very nature of empowerment, being a multifaceted concept, which is not readily quantifiable (Oxaal and Baden 1997).

A solution is represented by restricting the area of empowerment to the economic dimension or the agricultural dimension. These two dimensions are not necessarily overlapping, even though in highly underdeveloped rural areas, this is likely the case. In the economic and agricultural dimensions, gender gaps are quantifiable as being differences of ownership or access to numerable assets, resources, or services together with the participation in decision-making in private and public institutions. However, as previously mentioned, some relevant dimensions of women's empowerment are noneconomic and nonagricultural; nonetheless according to Alkire and colleagues, there is strong evidence to support empowerment of women in agriculture as being the key for growth, development, and recognition of the importance of women (Alkire et al. 2013).

The Women's Empowerment in Agriculture Index (WEAI) is considered to be "the first comprehensive and standardized measure to directly capture women's empowerment and inclusion levels in the agricultural sector." The index builds on recent research to develop indicators of agency and empowerment that propose domain-specific measures of empowerment obtained using questions that can be filled in individual or household surveys. The index was developed by IFPRI (International Food Policy Research Institute), OPHI (Oxford Poverty and Human Development Initiative), and USAID within the Feed the Future initiative, to track the inclusion, agency, and empowerment (relative and absolute) of women in the agriculture sector and to identify the progress in the fight against the obstacles and constraints faced by rural women (IFPRI et al. 2012).

Alkire and colleagues developed the index by linking it to an acute conceptual work grounded on her previous papers which permitted to operationalize the concept of women's empowerment in rural areas in an individual and context-specific measurement which is entirely composed of quantitative variables. The WEAI measures the involvement of women in agriculture to provide tangible data about the extent and share of

disempowerment among rural women considering two subindexes: the five domains of empowerment (decisions over agriculture production, access and power over productive resources, control over use of income, leadership, time use) and the gender parity index (reflecting the percentage of women who are empowered in their households), where the 5DE is weighted by 0.90 and the GPI is weighted by 0.10.

The WEAI, despite its limitations, is a promising tool which is starting to be used in developing programs around the world, and according to its creators, it will be useful to compare among different time references and regions the dimensions in which women are still disempowered in agriculture as well as the gap that needs to be closed for women to reach the same level of empowerment of men (Alkire et al. 2013).

Concluding Remarks

There is a broad consensus that if gender inequalities are addressed in rural contexts, the result is improved food security, nutrition and agricultural productivity, reduced poverty, and enhanced climate resilience of households and communities (FAO 2011; IFAD et al. 2009, 2015). However, for these measures to be sustainable in the long term, the efficiency aspects need to be pursued jointly with other noneconomic empowering dimensions. Rural women's lower level of education, self-esteem, limited mobility, and exposure to other contexts and realities seriously limit their horizons, visions, and aspirations, whereas development according to Amartya Sen should specifically address and remove such unfreedoms leaving people with "little choice and little opportunity of exercising their reasoned agency" (Sen 1999).

Moreover, rural women need to be actors of their own development. They need to be relieved from the androcentric burdens of care work and gender-based violence; they need their voices to be heard so that they will be able to increase their own agency and confidence and, as Sen would put it, have the "freedom to lead the lives that they

would choose to lead” (Sen 1992). To meet rural women needs, development approaches need to be gender transformative rather than gender sensitive and address social norms that are the root causes of gender inequality rather than focus exclusively on what should be understood as symptoms of these causes as unequal access to assets (Bishop 2017).

Introduction

The agricultural sector is stereotypically viewed as a masculine domain with a heavy emphasis on physical labor and mechanized fieldwork, yet women are responsible for a comparable portion of agricultural labor. Depending upon the region and the type of agricultural activity, women can account for as little as 20 % of the labor force, such as in the case of Latin America, or upward of 60 % in areas such as Lesotho, Mozambique, and Sierra Leone. On average in developing nations, women comprise 43 % of the agricultural labor force (FAO 2011). Women's work is conducted in a multitude of settings including, but not limited to, commercial or industrial farming, subsistence farming, organic farming, and the raising and production of livestock. Accurate output numbers are difficult to calculate as women are frequently underrepresented in the agriculture industry due to perceived gender roles and the belief that women are expected merely to help on family farms and do not constitute paid laborers. As a result of this, women are often referred to as the "invisible" worker. In a study of women in agriculture in Egypt, the rate of women's unpaid labor carried out within family settings is almost four times that of unpaid male labor (El-Tobshy 2005, p. 122). In rural areas, women make up the bulk of subsistence farmers, using their production skills to ensure food security, and their work often remains unaccounted for. Additionally, identifying accurate representation of female labor is

further complicated when accounting for hours worked, not just the numbers of individual contributors (FAO 2011).

Women's relationship to agricultural work has largely been a reaction to male roles and decisions, as women tend to fill the gaps and respond to demand created by the absence of men.

Modern trends show that men are choosing to leave farm enterprises and rural lifestyles for more lucrative jobs, except in the incidence of possessing ownership and supervisory roles (FAO 1998). As agriculture is increasingly becoming "women's" work, making it more likely to be perceived as possessing feminine responsibilities and characteristics, it is decreasing in status and desirability (Hammami 2005, p. 59). This shift in the agriculture sector, coupled with the idea that women are not capable of physical labor or working supervisory positions, limits responsibilities and tasks to remain overwhelmingly gendered, restricting the opportunities of female farmworkers. This results in inadequate career opportunities and persistent poverty. Traditional gender roles also discourage men from assisting with homecare responsibilities; therefore women are frequently required to work long, laborious hours on a farm or in a greenhouse and then must tend to household duties and childcare in their off-time. Compared to their male counterparts, these daily, exhaustive tasks perpetually put female agriculture workers at a disadvantage.

In many countries around the world, there exists some form of law that prohibits unequal compensation based upon gender, such as is the case in Kenya. However, in industries such as Kenyan floriculture, many women lack education pertaining to their legal rights (Dolan et al. 2003). Employers use this fact as a tool to conceal their efforts to skirt the requirement for equal pay based upon gender. Therefore women are oftentimes not compensated fairly for identical jobs. However, this is not to suggest that women do not face inequalities in the countries and regions that do more to legally protect women in the agriculture sector. In many parts of the globe, women's inequalities are often internalized behaviors and attitudes that create discrepancies in land tenure, which forces women to adapt their livelihood

strategies. They develop subsistence farming methods, they seek low-wage jobs, or, such as the case of more developed nations, women have begun to seek alternative farming methods to respond to market demand. Regardless of the individual's circumstances, women in the agriculture industry are at higher risk for injury and sexual harassment.

Land Tenure

A woman's role in agricultural work is primarily dictated by her relationship to the parcel of land that she is cultivating. Whether she owns the land, is renting the land, or is merely an employee of someone else who claims legal ownership to the land, her long-term success and financial stability are closely linked to the level of access to land tenure she experiences. The benefit to possessing property rights, or having land tenure, is that the owner can leverage the value of the property for the purpose of obtaining credit, they have control over decisions regarding use and development, and they can seek stability through long-term planning.

Women become the "invisible" worker when they marry into agriculture and enter an implied working contract on the family farm. Historically, family farms are a patrilineal inheritance and becoming a farmer's wife is not only a marital status, but it often becomes an uncompensated job. The marriage comes along with the expectation that a woman works alongside her husband to assist with operations on the farm (Prügl 2011). Very rarely does the marriage result in a legal partnership that would grant the certain benefits of landownership. The women in these situations have no right to sell the land, do not have any access to the value of the land, and are excluded from decision-making processes, therefore becoming exploited workers (Prügl 2011). In some instances, particularly in sub-Saharan Africa, women are viewed as owners of a crop with the right to cultivate the land and control the income from their crops, but are not explicit owners of the land, therefore lacking the ability to transfer and control the parcel. Their income and stability remains in the

hands of the predominantly male landowners of her community (Gray and Kevane 1999).

Women-owned and women-operated farms, despite observing some growth in the last few decades, are uncommon, particularly in developing countries. Since 1978, women-operated farms in the USA have grown by only 9 %, making up a mere 14 % of all farm operations in the country. Few of these farms reach industrial scale and most have annual sales that total less than \$10,000 USD (Wallace and Marshall 2013 pp. vii–viii). Industrial farming is highly dependent on nonowner farmworkers (Wells 2013, p. 20), and obtaining the vast amount of land required to be considered a large commercial farm requires great personal capital. Unless they inherit farmland, women simply lack the resources to make the leap from small-scale to large-scale farming. Other Western countries have observed similar trends and have attempted to combat female underrepresentation in agricultural work. For example, much of Europe has attempted to utilize gender mainstreaming, which assesses the potential for unequal implications of law and regulation on individuals due to gender (Prügl 2011). However, there are many factors outside of legal barriers that discourage female farmers from land ownership and agricultural work that are difficult for paradigms like gender mainstreaming to address. Gender norms, and the belief that women are caretakers and farmer's wives first and actual "farmers" last, perpetuates a lack of an effective transfer of agricultural knowledge from men to women (Trauger 2004) and subsequently preserves patrilineal land transfer.

Not only is access to land ownership an issue, but *stable* access to land use presents problematic circumstances for women who grow crops for food or financial security. Until recently in sub-Saharan Africa, most land has had no title or registration process to prove land ownership. In the past several decades, there has been a push to create a documented title system to increase financial stability and to increase access to the privileges associated with land ownership. Unfortunately, women had more access to land prior to the formal titling process as legal ownership has been granted to the male head of the household as

opposed to married couples (Gray and Kevane 1999). Traditional customs regarding the transfer of resources between families through marriage, coupled with population growth and land degradation, has made the bequeathing of land to daughters and women more complicated as men fear losing land and thus restrict their land to the use of their sons (Gray and Kevane 1999). Therefore, women must have the permission of men to use their fallow land or must develop working agreements at the discretion of landowners in order to grow crops. As previously mentioned, they can control the income associated with their yield, but the security of multi-seasonal land access to grow crops is absent and presents long-term instability for these women.

The impacts of the lack of access to land tenure extend beyond the financial security of the woman, as renting or continuously using land for short-term production provides little incentive to invest in sustainable practices. The result can be declining productivity of the soil and land and increased environmental degradation (FAO 1998).

Livelihood Strategies

Depending on location and economic status, women have adopted many different methods to utilize farming not only as a source of income but also as a means by which to increase food security and access to healthier nutrition. In response to the lack of access to land tenure, women have developed strategies of subsistence farming, off-farm work, and manipulating legal relationships for financial and survival purposes.

Almost universally, women are responsible for all aspects of home food preparation, from obtaining food and the fuel needed to cook it, to storage and preservation of excess (Spring 2000, p. 1). Because of this daily immersion in nutrition and diet, women are more likely to engage in gardening or subsistence farming to increase their food budget (Spring 2000; FAO 1998). However, this form of crop production is consistently threatened by the demands of household resources as a woman is expected to maintain her other roles as homemaker in addition to the daily demands of

food production. It is characteristic of women farming in this style to possess few business skills and informal agricultural knowledge and to extend her food resources solely to close relationships consisting of family and neighbors (Spring 2000 pp. 7–8). However, subsistence farming is credited with helping to maintain more biological diversity within food crops, as women encourage cross-pollination and work to maintain an assortment of crops for medicinal, nutritional, and spiritual purposes (FAO 1998). When women develop the means with which to increase their production and subsequently take their excess yield to local markets, they elevate their status of production to small-scale farming. However, the income from small-scale farming is rarely enough to survive on, so female farm-owners often rely on a wide range of off-farm work for necessary extra income, which can include work outside of the agriculture sector (Hoppe and Korb 2013).

Additionally, small-scale women farmers are more likely to develop other forms of capital such as social capital and human capital. By collaborating with other women, they manipulate their resources to secure the ability to produce food and cash crops. In sub-Saharan Africa, in response to inequalities surrounding the titling process and the complications that can arise from a man having multiple wives, women have been known to go into agriculture production with their sons to avoid the instability of farming with their husband. Additionally, women in sub-Saharan Africa have entered legal arrangements with other women to secure land for food production (Gray and Kevane 1999). Women will stay in less than satisfactory marriages or maintain marriages but will not live with their husband, in effort to hold onto land to use for food and crop production. Some women will collaborate with other women in large groups, purchase land, and share the workload while dividing the profits (Spring 2000, pp. 12–13).

Paid Labor

Industrial farming is heavily reliant on nonowner farmworkers (Wells 2013), and much of the paid

labor in the agriculture sector occurs on large-scale commercial farming operations. Due to the combination of the seasonal nature of crop production, pervasive low wages, and dangerous working conditions, the agriculture industry frequently attracts uneducated women, families living in poverty, migrant workers, and migrants seeking relief from political unrest. These marginalized groups provide a continuous supply of cheap and willing labor; however farm work is rarely sought as a solution to escape poverty or to better one's career choices. Farm work in this setting is simply viewed as a means to an end. The agriculture industry in the USA relies heavily on Mexican migrant labor, and over the past century, the continuous response of foreign workers to labor shortages in the USA has created an irrepressible relationship between cheap Mexican labor and US agriculture (Wells 2013, p. 20). In the case of a study of Mexican female migrant workers on US commercial farms, women interviewed described work on the farm as "a physically grueling, dead-end job that will leave you, after 30 years of employment, broken-down and financially insecure" (Wells 2013, p. 43). They admitted to never wishing that career for their children; however women commonly see farm labor as the better option to other forms of oppressive employment such as domestic service (Wright and Madrid 2007).

Additionally, female workers that cross borders for employment typically have little education and are living in poverty. This coupled with the seasonal nature of their employment results in annual migration back to Mexico to seek other employment in the offseason (Waugh 2010). If the work is seasonal, by nature of short-term contracts, it is difficult for workers to organize for better working conditions or pay. In the instance of year-round operations, particularly in warmer climates or in greenhouse operations, supervisors and employers of multiple businesses under different ownership may frequently work together to manufacture seasonal-like employment by offering short-term contracts and continually rotating workers, thus also making it difficult for permanent workers to organize (Talcott 2003).

Health Risks and Gendered Discrimination

Farming is known as one of the most dangerous occupations because of the use of heavy machinery, repeated close proximity to large animals, risk of chemical exposure, and the potential for long hours with highly repetitive tasks (Wells 2013). Gendered responsibilities and jobs often develop in response to the perceived roles of women as caretakers and homemakers and men as the primary source of household income. Therefore, women experience a lack of access to promotion or advancement and frequently undertake the less desirable roles. Women who accept employment as paid laborers, particularly in developing nations or in the instance of migrant workers, often do it out of necessity, such as the case of single motherhood or when seeking supplemental income (Wells 2013). The potential then arises for women to feel pressured to remain in hazardous working conditions or tolerate inappropriate behavior from supervisors and coworkers. Women in the agriculture sector are disproportionately affected by occupational hazards, sexual harassment, and gendered discrimination, all of which can be exacerbated by being of ethnic or racial minority, economic status, or farming in a developing country where little regulation and oversight is mandated.

One of the most observable examples of these intersecting characteristics hindering employment opportunities would be in the Colombian floriculture industry. The owners of the companies producing cut flowers in Colombia are overwhelmingly white, westernized, and educated men. Administrative and supervisory roles consist of light-skinned, middle-class workers, with women only climbing as high as the lowest administrative positions. The laborers are typically dark-skinned and overwhelmingly female (Wright and Madrid 2007). Laborers in the agribusiness sector rarely earn more than the minimum wage, and in the study of a cut flower operation in Colombia, the retail value of what a woman picked for a day was upward of 300–400 % of her daily pay (Wright and Madrid 2007). It is not uncommon that men are granted

permanent positions that consist of supervisory positions, machine operators, foremen, and mechanics. Women often are the “pickers” or the seasonal field labor which often results in more of them performing more arduous work (Wells 2013, p. 26). Women are believed to be incompetent in operating machinery (Hammami 2005, p. 67) and are also believed to be incapable of performing heavy, manual labor. However, the lack of access to mechanized assistance compounds the amount of manual labor women actually perform, which puts them at greater risk for injury, particularly overuse injuries and muscle strains (Wells 2013, p. 26).

Furthermore, in the male-dominated agriculture industry, women’s reproductive roles prove to be a barrier to obtaining permanent employment, and pregnancy often restricts women to seasonal positions. In the study of Kenyan floriculture, women reported having to take physical exams to qualify for permanent employment and pregnancy resulted in a failed physical. Of the nine companies observed, only three offered maternity benefits to seasonal employees. The lack of paid maternity leave results in women seeking more abortions, feeling the pressure to hide their pregnancy from employers, and working until the day they deliver. Women reported the feeling of being heavily surveyed if they ever exhibited signs of being ill and were under constant fear of dismissal (Dolan et al. 2003).

Additionally, women are at higher risk for repeated chemical exposure and skin and respiratory issues for multiple reasons. In the previously mentioned study of numerous Kenyan cut flower operations, female workers reported higher rates of illiteracy and therefore experienced disproportional exposure to chemicals because of improper mixing and improper handling of chemicals (Dolan et al. 2003). In comparison with permanent workers, seasonal workers are also less likely to be issued their own personal protective equipment (PPE), and due to output pressures, women expressed that they were less likely to utilize PPE because it obstructed their movement and slowed down production (Dolan et al. 2003).

Because of the disproportionate amount of men in supervisory and hiring roles, women in

the agriculture industry are at high risk of sexual harassment. In many cases, women are dependent on men during the hiring process, men evaluate their work, and they work in crews or teams led by men, setting up a power dynamic that can easily permit sexual harassment. The lack of female leadership and supervisory roles can also dissuade the reporting of inappropriate behavior. In the study of Kenyan floriculture, sexual harassment was reported on all farms. Supervisors were known to request sexual favors in exchange for employment, time off, and bonuses, and women expressed fear of dismissal if they did not cooperate (Dolan et al. 2003). In a study of migrant field workers in the USA, the inherent working conditions and literal environment put women at higher risk for sexual harassment. By working in remote areas, and oftentimes visually hidden by the actual vegetation of the farm fields, unwanted comments and stares, grabbing, and even rape were perpetrated unto the female employees by their male supervisors (Waugh 2010). These women also expressed that a lack of English-speaking skills and their legal status affected their ability and willingness to report any harassment for fear of dismissal or retaliation. Overwhelmingly, it is the power structures at play that disproportionately endanger female farmworkers. Because the agriculture industry is controlled primarily by men, sexist views and behaviors have become entrenched in daily operations.

Alternative Agriculture

In response to gender discrimination in the agriculture sector, restricted access to land tenure, formal agriculture education, and opportunities in industrial farming, women have recently begun to carve out a corner of the market to address the growing demand for organic and sustainably produced food. Not only have women flourished in this market for practical reasons, but for some, it represents a movement rooted in feminist values that provides an opportunity to challenge patriarchal norms and to view food systems as a relationship facilitated through the product.

Prior to the 1990s, women's input into German agriculture was experiencing a decline that started to reverse when an intensification in organic farming was observed (Prügl 2011). Similar trends have been observed in other developed countries, as evidence suggests that women are more likely than men to adopt organic farming practices (Prügl 2011, p. 40). Because small-scale organic farming is labor intensive and largely unmechanized, and women are less invested in the practices of industrial-scale farming, it can present an easier transition, and women are more likely to be critical about the impacts of non-organic practices on sustainability and environmental issues (Trauger 2004; FAO 1998). Women are also more likely to be concerned with the conditions that agricultural workers and farm laborers have to cope with (FAO 1998) and willingly choose to forgo synthetic chemical use and deemphasize the mechanization of farm operations (Trauger 2004).

The implication of women being overrepresented among small farmers is that they are considerably more focused on local markets, concerned for the community they are providing for which is congruent with the perception that "community work" is women's work. Women participating in these farm trends also express the idea that organic agriculture is not enough, but emphasis on local production is equally important primarily because of the resources required to transport product over great distances (McMahon 2002).

Arguably, not only have these agricultural practices been overwhelmingly embraced by women because of their access to only small parcels of land and lack of education in regard to large-scale farming but also as a response to their relationship to the industry being refereed primarily by their male counterparts. It can be seen as an act of liberation from male oppression and as a way to defy cultural stereotypes. Observing farming through a feminist lens places the emphasis of agriculture on the relationships of those invested in the process, not just simply food production. The relationship exists between those who produce the food, transport, and sell the food and eventually those that consume the food

(Trauger 2004). Small-scale, organic farming acts as a cultural resistance that challenges capitalism and the commodification of life that occurs on industrial-scale farms (McMahon 2002).

Additionally, small-scale farms provide the farmers with the opportunity to maintain biological diversity and to better accommodate long-term production of the land through crop rotation, less tilling, and the continual replenishment of organic matter into the soil. Historically, women have taken charge of saving seeds and experimenting with hybridization of indigenous species, which has been recognized as an essential component of food security (FAO 1998). Because of the link between activism and feminism in small-scale farming, whether they are male or female operated, they are becoming politically and culturally feminized, which carries the implications that they are inefficient, nonrational, and unproductive (McMahon 2002). Attitudes within female farming communities would argue otherwise, as they view their role in the local and global communities as a positive force, intentionally responding to the inefficiencies of agribusiness, addressing environmental degradation, increasing global food security, and combating gender inequality. When women are privileged to the same access to resources that their male counterparts have, women generate higher productivity (FAO 1998), and it is on the small-scale farm that women have leveraged their resources to find their niche. While small-scale and alternative farming seem to be a multifaceted approach to tackling the issues women face in the agriculture industry, it is by no means a universal option for women. To address all the inequalities observed would require the implementation of more than just laws and regulations. It would require an entire reconstruction of gender perceptions and would demand the value of women in all dimensions to be recognized.

World Trade Organization: Sanitary and Phytosanitary Agreement

The World Trade Organization (WTO) Agreement on the Application of Sanitary and Phytosanitary Measures (SPS Agreement) is an

international agricultural trade agreement that allows countries the ability to implement measures “to protect human, animal or plant life or health” as long as the measures are not “arbitrary or unjustifiable discrimination between Members where the same conditions prevail or a disguised restriction on international trade.” The preamble to the agreement continues to establish the purposes of the agreement, which include the establishment of (1) multilateral framework of rules and disciplines for SPS measures to minimize their negative trade effects, (2) harmonized international standards, and (3) more elaborate rules than what the General Agreement on Tariffs and Trade (GATT) provides, in particular Article XX (b). This agreement grew out of the negotiations of the WTO Agreement on Agriculture (Agriculture Agreement, Specifically Article 14) and represents a rare sanctioned limit on free trade based on the risk to animal, plant, and human life.

The basic unit of the SPS Agreement is the “SPS measure,” and the SPS measure is defined in Annex A(1) as a two-part definition. An SPS measure, generally speaking, is a (1) measure with (2) a purpose:

SPS measures include “all relevant laws, decrees, regulations, requirements and procedures including, *inter alia*, end product criteria; processes and production methods; testing, inspection, certification and approval procedures; quarantine treatments including relevant requirements associated with the transport of animals or plants, or with the materials necessary for their survival during transport; provisions on relevant statistical methods, sampling procedures and methods of risk assessment; and packaging and labeling requirements directly related to food safety.

The above measures must be applied for one of the following four **purposes**: “(1) to protect animal or plant life or health within the territory of the Member from risks arising from the entry, establishment or spread of pests, diseases, disease-carrying organisms or disease-causing organisms; (2) to protect human or animal life or health within the territory of the Member from risks arising from additives, contaminants, toxin or disease-causing organisms in foods, beverages or feedstuffs; (3) to protect human life or health within the territory of the Member from risks arising from diseases carried by animals, plants or products thereof, or from the entry, establishment or spread of pests; or (4) to prevent or limit other damage within the territory of the Member from the entry, establishment or spread of pests.”

The SPS Agreement further dictates the process by which an SPS measure can be established by a member country. The member is to perform a risk assessment and determine the appropriate level of protection based on the risk assessed (Article 5). The risk assessment should include (Article 5.2): “available scientific evidence, relevant processes and production methods; relevant inspection, sampling and testing methods; prevalence of specific diseases or pests; existence of pest- or disease-free areas; relevant ecological and environmental conditions; and quarantine or other treatment.” In determining the appropriate level of protection (sometimes termed ALOP), members should minimize negative trade effects (Article 5.4) and avoid arbitrary or unjustifiable distinctions in appropriate levels in different situations that would result in discrimination or a disguised restriction on international trade (Article 5.5), in order to ensure that measures are not more trade-restrictive than required (Article 5.6). Specifically, members should consider economic factors (Article 5.3) such as: “the potential damage in terms of loss of production or sales in the event of the entry, establishment or spread of a pest or disease; the costs of control or eradication in the territory of the importing Member; and the relative cost-effectiveness of alternative approaches to limiting risks.” If the available scientific evidence is insufficient to assess the risk, the member can implement a provisional measure, but the member is required to seek additional information and review the measure within a reasonable period of time (Article 5.7). Finally, other members can request an explanation for a member’s SPS measure (Article 5.8).

The SPS Agreement further establishes broad-based principles for SPS measures. The basic obligations required for all SPS measures include that a measure is applied only to the extent necessary, is based on scientific principles, and is not maintained without sufficient scientific evidence, except as provided for in paragraph 7 of Article 5 (Article 2.2). The SPS Agreement encourages that member countries apply international standards, guidelines, and recommendations, especially those developed by the International Office of Epizootics, the Codex Alimentarius

Commission, and the organizations operating under the International Plant Protection Convention (Article 3, especially 3.4).

The SPS Agreement permits adapting to regional variation in prevalence (Article 6), requires that members respect foreign equivalent measures that meet their appropriate level of protection (Article 4), and mandates that members enact measures transparently providing notification internationally (Articles 7 and Annex B). Inspection and control procedures are to be handled by member governments (Article 8) according to specific procedures (listed in Annex C). The SPS Agreement acknowledges that developing countries may require technical assistance (Article 9) and special and differential treatment (Article 10). Finally, the agreement establishes a committee for administration (Article 12), a dispute settlement mechanism (Article 11), and some flexibility for implementation for developing countries (Article 14).

WTO Disputes

The SPS Agreement disputes (cases) all involve four elements: an exporting country with a risk and an importing country with a measure to prevent the risk. The central question then is whether the measure balances the risk or not. For most of the cases tried at the WTO so far, the measures were clearly adopted without enough consideration of either the risk or the severity of the measure's application.

The following cases consider provisions of the SPS Agreement and a brief notation of the four elements and the case's SPS Agreement determination:

- Australia – Measures Affecting Importation of Salmon DS 18
 - Australia was imposing import requirements for uncooked salmon from Canada.
 - Australia was concerned about salmon diseases and disease agents.
 - Australia required quarantine and heat treatment requirements for the imported salmon.
 - The Appellate Body found that the Australian measures were not based on a risk assessment and thus were inconsistent with Article 5.1 and by implication Article 2.2 and inconsistent with Article 5.5 and thus by implication Article 2.3 (Para. 279(d), (e)).
- The Article 21.5 Recourse Panel Report further found that the amended “consumer-ready” requirement was inconsistent with Article 5.1 and by implication Article 2.2 and also Article 5.6 (Para 8.1(ii), (v)). Also, the Tasmanian measure was also inconsistent with Article 5.1 and thus Article 2.2 as well (Para. 8.1 (vii)).
- European Communities – Measures Concerning Meat and Meat Products (Hormones) DS 26, 48
 - The European Communities raised concerns about imported US and Canadian beef, based on the practice of giving cows hormones as part of its agricultural production.
 - There were six hormones at issue.
 - The EC passed regulations banning the use of hormonal products in meat production.
 - The Appellate Body refined the Panel's application of the SPS Agreement specifically in the relationship between Articles 3.1, 3.2, and 3.3 (Para. 253(g), (h)), the consideration of the Precautionary Principle (Para. 253(c)), the relationship between Articles 5.1 and 2.2 (Para. 253(l)), and the understanding of risk assessments (Para. 253(j)). The Appellate Body further upheld the Panel's determination that the EC measures were not consistent with Article 5.1 (Para. 253(l)) and that Article 3.3 must comply with Article 5 (Para. 253(i)).
- Japan – Measures Affecting Agricultural Products (Agricultural Products II) DS 76
 - The United States claims that the testing requirement for eight agricultural products – apples, cherries, peaches (including nectarines), walnuts, apricots, pears, plums, and quince – is not consistent with the SPS Agreement.
 - Japanese quarantine and varietal testing was implemented to detect the presence of codling moth, a pest of concern.

- Japanese measures requiring testing for each varietal found to be maintained without sufficient scientific evidence under Article 2.2 (Para. 143(a)), and not justified as a provisional measure under Article 5.7 (Para. 143 (b)). The measures are also inconsistent with Article 5.1 because they are not based on a risk assessment (Para. 143(f) and inconsistent with Article 7 (Para 143(e)).
- Of note, the Panel, in its report, provides the definition of sufficient scientific evidence in Article 2.2, as the rational relationship between the SPS measure at issue and the risk assessment performed (Para 8.28).
- Japan – Measures Affecting the Importation of Apples DS 245
 - US apples were subject to import restrictions imposed by Japan.
 - The concern was over the potential for fire blight.
 - Japan imposed quarantine restrictions as SPS measures.
 - The Appellate Body affirmed the Panel’s finding that the measure was maintained without sufficient scientific evidence under Article 2.2 (Para. 243(b), not justified as a provisional measure under Article 5.7 (Para. 243(c)), and the measure was not based on a risk assessment (Para. 243 (d)).
 - In the Article 21.5 Recourse Report, the Panel found that Japan’s amended measures were still maintained without sufficient scientific evidence under Article 2.2 (Para. 9.1(a)), not based on an appropriate risk assessment under Article 5.5 (Para. 9.1(b)), and more trade-restrictive than necessary under Article 5.6 (Para. 9.1(c)).
- European Communities – Measures Affecting the Approval and Marketing of Biotech Products DS 291–293
 - The United States, Canada, and Argentina each individually brought cases against the European Communities for their regulations involving biotech or genetically modified products.
 - There were approximately 25 genetically modified products, including various strains of maize (including food and sweet maize), oilseed rape, fodder and sugar beets, and cotton.
 - European regulations involved a moratorium and specific approval procedures for biotech marketing approvals as well as safeguards to be implemented.
 - The Panel found that the moratorium was inconsistent with Article 8 and Annex C (1) (Paras. 8.14, 8.34, and 8.50), and the product specific measures were inconsistent with Article 8 and Annex C(1)(a) (Paras. 8.18, 8.38, 8.53) and that the safeguard measures were not based on a risk assessment as required by Articles 5.1, 5.7, and by implication 2.2 (Paras. 8.21–8.30, 8.41–8.46, 8.56–8.62).
 - Of note, the Panel specifically stated that in its determination, it “did not examine whether biotech products were safe” (Para. 8.3).
- United States, Canada – Continued Suspension of Obligations in the EC and Hormones Dispute DS 320–321
 - The United States and Canada were sued in response to their continued application of retaliatory measures regarding European beef imports that were banned because of the use of hormones in cattle.
 - Europeans had changed their regulations in response to the WTO litigation in the underlying EC Hormones dispute (DS 26, 48).
 - The Appellate Body reversed the Panel on the question of the measures not being based on a risk assessment provisional or otherwise but stopped short of considering the measure any further (Para. 736(c)(i, iii, iv, v, vi), (d)(i, ii, iv, vi)).
- Australia – Measures Affecting the Importation of Apples from New Zealand DS 367
 - New Zealand made a claim that Australia had implemented SPS measures against its apples inconsistent with the terms of the agreement.
 - The risk of infestation of three apple diseases was identified: fire blight, European canker, and apple leaf-curling midge (ALCM).

- Australia imposed 16 different import restrictions based on the risk posed by the 3 diseases.
- The Appellate Body found that these measures were SPS measures and that they were not based on a risk assessment and were inconsistent with Articles 5.1 and 5.2 and by implication Article 2.2 as well (Para. 444(a)–(b)).
- United States – Certain Measures Affecting Imports of Poultry from China DS 392
 - The US Congress implemented a ban on any rules permitting Chinese poultry imports into the United States.
 - This legislation Section 727 of the Agricultural Appropriations Act of 2009 (Pub. L. 111-8) was enacted based on sanitation issues reported in the news.
 - The Panel found that the measure is not based on a risk assessment as required in Articles 5.1 and 5.2 (Para. 8.1(a)) and independently found that the measure was also maintained without sufficient scientific evidence under Article 2.2 (Para. 8.1(b)), as well as Article 5.5 (Para. 8.1(c)), and, by implication, Article 2.3 (Para. 8.1(d)) and finally inconsistent with Article 8 and Annex C(1)(a).

country uses to justify its ban of certain agricultural products because of sanitary or phytosanitary reasons.

There are a couple of ethical considerations that arise from this reliance on scientific evidence to support an SPS measure. First and foremost there is the time lag involved between the identification of a potential risk, the research of that risk, the scientific peer review and publication of that risk, and the consideration of the impact of the risk over time. In the EC Hormones decision, the discounting of the “Precautionary Principle” effectively closed the door on prospective concerns about the risk that may be possible (Appellate Body Report, Paras. 123–125), requiring that “provisional” scientific study at the least must be available. For some, that requirement of provisional scientific study is an ethical dilemma in and of itself. But, interestingly enough, the discussion of future research that may change the view of the risk in the United States and Canada Continued Suspensions reopened the door to the imposition of an SPS measure in time with the scientific evidence to justify it in the future (DS 320 Appellate Body Report, Paras. 701–712). However, there needs to be a reason for the SPS measure, as the Japan Agricultural Products case intones, there has to be a rational basis for the measure based on an objective assessment of the risk (Panel Report, Para. 8.28). Thus, there is a time lapse between the trade of a product and the scientific understanding of the risk.

Ethical Implications of the SPS Agreement

The SPS agreement, like the Agreement on Agriculture, does not on its face raise any ethical issues about food per se. In fact, the SPS Agreement is the rare “anti-trade” agreement in the WTO as it acknowledges that there will be certain occasions where the trade in agricultural products cannot be permitted because of the risk to life and health. However, the SPS Agreement bases its underpinning on the underlying scientific evidence supporting the limitation. Thus, the SPS Agreement must accommodate the uncertainty of the scientific method, and trade professionals must interpret the research findings of scientists that a

A decision has been made by the WTO in the SPS Agreement to opt for a “wait and see” approach versus a “do no harm” approach. This does seem counterintuitive to the primal desire for all living things to protect themselves but instead says that a nation cannot impose a measure “out of fear.” Ultimately the SPS Agreement makes the assumption that all agricultural products traded in international commerce are safe for consumption and pose no risk, unless that risk has been previously identified, measured, and then codified into the most limited ban possible. So countries in abiding by the SPS Agreement must overcome this primal urge to regard new or different agricultural products with suspicion and concern of potential risk and embrace a more risk-tolerant

approach that every new and different product is in fact safe until proven otherwise. This is a difficult paradigm shift to make, especially given that some invasive species once brought into an area cannot be eradicated, and there is no scientific understanding for novel foods (such as biotech) of the effects of their long-term use.

Second, another ethical consideration that arises is the true intent of the SPS measure. Countries implementing bans of agriculture products based on risk and safety may be trying to stave off foreign competition rather than support a prospective determination of safety. How does one determine the intent of an SPS measure and whether the protection of the consumer (a good reason to limit or ban trade) is intended versus the protection of a country's domestic agriculture sector from foreign competition (a bad reason to limit or ban trade)?

There are limits to the conversations that science and law can have regarding the risk and decisions about a particular action or ban. The scientific method can model a particular behavior and may be able to provide some idea of the repeatability of that behavior in another environment based on the conditions described in the initial experiment. But, the justification that a country has to apply a ban on agricultural trade based on that scientific evidence has to be considered against the likelihood that the scientific evidence presented accurately models the same conditions of the importing country. That discussion about the modeling of the science against the conditions of the importing country will require a legal determination of the likelihood that the scientific proof offered is "sufficient" to justify the ban (as contemplated in Article 2.2 of the SPS Agreement).

That application of the scientific evidence has to be further interpreted against the intention of the scientist making the call and the financial or other influences that may come from the importing country's government. Thus, there is an assumption made about the objective and impartial nature of science, and from an ethical perspective, the science may be considered above or separate from the economic influences of governments, even though much science is in fact

funded by the governments. In the end, the richer the government, the more robust the science it can fund. To what end can a developing country implement an SPS measure or fight an SPS measure against a developed country?

As a final note, the SPS Agreement embraces the scientific calculation of risk and asks that the country set an appropriate level of protection based on that risk. It's a difficult decision to make: How prudent should a country's response to a risk be? What is an appropriate level of protection?

Science can identify minute risks and risks that can be only manifested over a long period of time. Thus, the appropriate level of protection will have to be adjusted accordingly; otherwise, risk aversion may be seen as disguised economic trade restriction. And yet, a government is subject to the political will of its people, and thus negotiation of the risk appetite for a particular nation's citizens is a dangerous political proposition. Food security is not just about food availability but also food safety. And as discussed in the agreement on Agriculture discussion, food insecurity creates political instability. A nation's population may not have as great a risk appetite as the rest of the world would demand, which pits a nation's government between its people and the global agricultural trading sector. In the end, the countries controlling the science control the debate about risk, protection, and safety.

Introduction

International trade agreements are formal accords under international law involving two or more

countries. Multilateral trade agreements are negotiated by the members of the World Trade Organization (WTO) and set out rules and regulations for the conduct of international trade among the majority (164) of sovereign nation states (about 164). All WTO members must agree to the negotiated trade provisions and are required to define specific commitments in national legislation to insure consistency with the rules. Similar procedures are followed for regional and bilateral – also known as “preferential” – trade agreements. If a party to an international trade agreement violates any of the commitments it has made, other parties may seek redress through the organization governing the agreement. To handle these situations, trade agreements include procedures for dispute settlement that usually involve the establishment of expert panels to hold hearings on the case and to render a judgment based on the provisions of the trade agreement in question. The following discussion is focused on WTO dispute settlement operations because they are the best known procedures for resolving international trade disputes. They are also widely criticized for their insensitivity to national and international laws on environmental protection, human rights, and other global concerns. In addition, some worry that adjudicating complaints through the WTO dispute settlement mechanisms can be costly and may require legal expertise not easily found in many developing countries.

WTO Dispute Settlement (DS) Procedures

Toward the end of World War II, world leaders created international legal institutions and organizations to administer them. In addition to the United Nations, the International Monetary Fund, and the World Bank, they hoped to create an International Trade Organization (ITO). A proposal for such an organization was developed at a conference in Havana, Cuba, in 1948, but this agreement was blocked by the United States. A somewhat earlier and less ambitious agreement, the General Agreement on Tariffs and Trade (GATT) took on some of the functions

envisaged for the ITO. The WTO, created in 1995, absorbed the GATT as well as other multilateral trade agreements such as the Agriculture Agreement and the General Agreement on Trade in Services (GATS). The primary objective of the GATT and WTO is to promote trade liberalization and to offer governments an avenue for avoiding the protectionist trade policies that had seriously impaired the functioning of the global economic system during the 1930s. Under both the GATT and the WTO, periodic trade negotiations, often referred to as “rounds,” have been organized to develop new rules to promote freer trade. The Uruguay Round, which created the WTO, was the eighth round of trade negotiations. A ninth round known as the Doha Development Round (DDR) or the Doha Development Agenda (DDA) was launched in 2001. The DDR covers some 20 areas of negotiation all of which have to be agreed upon as a complete package before the final communiqué is issued. Although there has been progress in some of the negotiations, final agreement has not been reached.

In addition to organizing multilateral trade negotiations, the WTO is also in charge of resolving trade disputes between member states. Dispute settlement (DS) procedures under the GATT were often ineffective because the decisions of the DS panels could be blocked by the losing party and, without clear time constraints for completion of the hearings and reports, cases often dragged on for many years without satisfactory resolution (WTO 2012a). The Uruguay Round agreements included strengthened dispute resolution mechanisms with fixed time lines for completion of the various steps in the process. Countries that believe that their economic interests have been harmed because another WTO member has violated the commitments it has made may elect to request “consultations” with the offending party. The consultations are aimed at finding a mutually agreeable resolution of the dispute and can last up to 60 days. If the consultations fail to settle the conflict, the Dispute Settlement Body (DSB), which is made up of the entire membership of the WTO, may agree to establish a DS panel of experts from countries not party to the dispute to hear the case (WTO 2012a). The panels are

supposed to complete their report within 6 months. The panel’s report is submitted to the DSB which can either accept or reject all or parts of the report and recommendations from the panel (WTO 2012a).

Decisions of the DSB can be appealed, and once a final decision has been adopted, parties that have been judged to have violated their commitments are expected to alter the offending trade policy or offer satisfactory compensation to the complainants. If the parties to the dispute cannot reach agreement that the policies at fault have been sufficiently altered to remove the harm or that adequate compensation has been negotiated, the complainants can request permission from the DSB to suspend their normal WTO obligations in order to retaliate by placing trade restrictions on exports from the losing party. A recent case on upland cotton illustrates the operation of the DS procedures. In September 2002, Brazil requested consultations with the United States concerning US policies for upland cotton (WTO 2014). The United States provides subsidies for cotton so that producers are sheltered from lower world market prices. These subsidies create incentives for increased production which further depresses world prices harming producers in other exporting countries (Peterson 2009). Brazil was joined by 16 other countries seeking to change the US policies charging that they violated US commitments made to comply with the WTO Agriculture Agreement. A dispute settlement panel was eventually convened delivering its report in September 2004 largely upholding Brazil’s position. The United States appealed the decision to a WTO agency known as the Appellate Body which again upheld most of Brazil’s complaint. In November 2009, Brazil was granted authorization to retaliate as the US policies had not been changed and adequate compensation had not been agreed upon (WTO 2014). The following year, the Brazilian government listed the US goods that would be subject to retaliatory tariffs but decided to hold off on their implementation while pursuing further negotiations with the US government and in return for compensatory payments to the Brazilian cotton industry (Chan 2010). The Brazilian government expressed the

hope that a more permanent solution to the problem might be achieved in the context of new farm policy legislation to be adopted in 2013 to replace the expired 2008 Farm Bill (WTO 2014). In October 2014, the parties to the dispute issued a memorandum of understanding that provided for a final payment of \$300 million to the Brazilian cotton industry and agreement by Brazil to terminate the dispute (USDA 2014).

Criticisms of the DS Procedures

The DS procedures of the WTO provide a way for countries to resolve trade conflicts. In the absence of such procedures, it is likely that trade disputes would rapidly escalate into full-blown trade wars. Trade wars are not precluded by the DS procedures: offending parties can always refuse to change their policies and complainants can then retaliate with trade barriers of their own. But the procedures offer the possibility that the parties will be able to find a solution short of a trade war, and they also have the added benefit of helping to clarify WTO and international trade law. Of course, there is no guarantee that these cases will be resolved amicably or speedily. The article by Hobbs (2014) on the Canada, US-EU beef hormone dispute in this encyclopedia describes a case that started under the GATT in the late 1980s and that was finally resolved only in March 2012. On the other hand, according to the WTO, 452 cases have been submitted to the WTO since 1995 and, of these, 150 are in consultations, 92 are being addressed by DS panels, and 202 have been withdrawn, terminated, or settled with recommended changes either implemented or in the process of being implemented. In only eight of these cases has an authorization to retaliate been requested or granted (WTO 2012b).

The apparent success of the DS procedures is overshadowed by the fact that some of the cases have been extremely controversial. Before examining two of these contentious cases more closely, it is useful to consider some broader criticisms of the WTO many of which carry ethical dimensions associated with the DS procedures. Singer (2004, page 55) identifies four main criticisms of the

WTO. The first is that it gives priority to commercial and economic interests over other considerations, such as environmental protection, that are of equal or greater value. The WTO is also criticized for undermining national sovereignty and for being undemocratic. Finally, some believe the WTO contributes to global inequality favoring the rich and large corporations in high-income countries over the poor. The first criticism is probably the most important and the one most closely connected to food and agricultural ethics. In examining this charge, Singer draws heavily on two controversial cases that were handled by GATT and WTO dispute resolution panels. He notes that the language in the WTO agreements allows countries to restrict trade to protect the environment, human rights, or other issues with social, political, and ethical dimensions (e.g., child labor). Based on his analysis of the Mexico-United States dispute over dolphin mortality associated with tuna fishing and the India-United States dispute over sea turtle endangerment connected to shrimp fishing, however, he concludes that commercial interests do indeed seem to trump environmental concerns in the DS process. Calle (n.d.) examines these and other controversial disputes and reaches similar conclusions. The tuna-dolphin and shrimp-sea turtle disputes will be examined in greater detail in the next section.

Singer appears to have mixed feelings about the charge that the WTO undermines national sovereignty. There is little doubt that the WTO and other institutions that increase interdependence among the nations of the world serve to constrain state sovereignty (see the article in this Encyclopedia by Peterson on “Food and Agricultural Trade and National Sovereignty”). Singer points to social contract traditions, noting that as in the case of citizens giving up some of their rights in return for the benefits provided by a state, so nations may choose to give up some of their room for maneuver in return for the benefits of access to the global trading system. On the other hand, as the WTO has extended its reach into areas such as the protection of intellectual property rights, the potential for conflict between legitimate government policy initiatives and

WTO rules may lead to unfortunate outcomes. Singer suggests that protection of patents on anti-retroviral drugs used in the fight against HIV/AIDS could have caused immense harm because these drugs are so expensive. Allowing generic substitutes would save millions of lives but might run afoul of the WTO agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPS). In this particular case, however, South Africa and other African countries were eventually able to import generic versions of the drugs at much lower cost without interference from the pharmaceutical industry or the WTO. WTO agreements and the dispute settlement procedures that support them do erode national sovereignty but whether this is a good or a bad thing depends on the particular circumstances.

The charge that the WTO is undemocratic is true in at least one sense: large nations such as China (population, 1.3 billion) have only one vote, the same as tiny countries such as Saint Kitts and Nevis (population, 39,000). Singer also criticizes an argument put forward by the WTO claiming that because decision making is done by consensus, the WTO is actually more democratic than organizations in which decisions are made by simple majorities. With almost no supporting argument, Singer asserts that this claim is false (page 75). He correctly notes that requiring consensus means that every member has a veto and such a voting system will inevitably favor maintaining the status quo because it is almost certain that some country would oppose any change that is proposed. But these implications of a unanimity voting rule do not inherently make such a rule undemocratic. Pareto optimality, defined as a situation in which no one can be made better off without making someone else worse off, is an important concept in welfare economics. If policy makers seek to achieve Pareto optimality, the only way to guarantee that outcome is through consensus voting. Many (including this author) reject the idea that Pareto optimality is a reasonable criterion for policy decisions because of the overly conservative nature of such a voting rule, but for matters of grave import, having the right to veto

objectionable changes may be thought by some to be critical (but see Sen 1970).

The final charge against the WTO is that it contributes to greater global inequality by favoring the interests of large private corporations which exploit the poor in low-income countries. Given that those making this claim often defend contradictory positions (e.g., cheap US maize drives poor peasants in Mexico off their farms while at the same time US policies on maize ethanol drive up the prices paid for tortillas by poor urban Mexicans), Singer elects to focus on the empirical question of whether or not global inequality has increased. He reviews a number of studies and concludes that statistical data and other information about income inequality are too unreliable to make a firm determination on this question. Since the publication of Singer's book, there has been a great deal of research done on national and global inequality. While the more recent work has not definitively resolved the question, there is a broad consensus that both inequality within countries and global inequality are increasing (Milanovic 2011). The role of the WTO in these increases is much less clear. The WTO was created to foster a liberal trading system on the grounds that free trade can be expected to increase general economic well-being. Most economic analyses recognize that trade liberalization can lead to lower incomes in uncompetitive industries but note that the gains to other sectors of the economy almost always are greater than these losses. For food and agriculture, there is good evidence that trade liberalization and other policy reforms would lead to substantial net benefits with higher commodity prices that benefit producers in low-income countries but that harm poor consumers in these same countries (see Peterson 2009).

Questions about the impact of the WTO on developing countries are related to another concern that has been raised about DS. Arguing a case before the DSB and the experts on the panel is complicated and requires expertise that may not be readily available in low-income countries. Mosoti (2006) and Bown and Hoekman (2005)

explain the low participation in DS cases by developing countries by noting the legal complexities and costs associated with the WTO procedures. If low-income countries are unable to defend their interests before the DSB, the entire system might be judged to be biased and unfair. Bown and Hoekman (2005) suggest providing legal services to low-income countries through international organizations, foreign aid, and non-governmental organizations. The DS procedures allow interested third parties to join other countries in filing complaints and this may be an avenue for increasing their participation in these processes. Poor countries such as Benin, Chad, Pakistan, and India joined with Brazil in the upland cotton dispute with the United States although only Brazil was granted authorization to retaliate when it was determined that the United States had not complied with the DSB ruling (WTO 2014). If current DS procedures do prevent full participation by the governments of low-income countries, reforms along the lines suggested by Mosoti (2006) and Bown and Hoekman (2005) would seem to be needed.

Tuna, Dolphins, and Turtle Excluder Devices (TEDs)

Singer (2004), Calle (n.d.), and others point to particular decisions by the DSB in support of their conclusion that the WTO favors commercial interests over other values, notably environmental values concerning endangered species and the protection of marine mammals. The decision in the dispute between Mexico and some other countries and the United States over tuna fishing methods in the Eastern Tropical Pacific that led to the deaths of large numbers of dolphins incensed the environmental community and still resonates as a case in which legitimate environmental concerns seem to have been overridden by the WTO's commitment to free trade. In the Eastern Tropical Pacific, tuna frequently swim below dolphins. The dolphins are easier to locate as they swim near the surface and it has been common for tuna fishers to use dolphin sightings to set their nets. The US Marine Mammal Protection Act (MMPA) adopted in 1972 restricts

imports of tuna captured with methods that lead to substantial dolphin killings (WTO 2012d). Mexico requested consultations on these provisions in 1991 arguing that GATT exceptions allowing the use of trade barriers for environmental purposes only apply to final products not the methods used to produce them. In addition, Mexico objected to the extension of US laws beyond US territory noting that the MMPA is not an international law. The GATT panel ruled in favor of Mexico agreeing with the argument that the GATT exceptions apply only to final products and concluding that countries are not free to impose their national standards on other countries (WTO 2012c, Perrin et al. 2002).

The Mexican government decided to drop the case, so the panel report was never adopted. Instead, Mexico, the United States, and other countries undertook direct negotiations aimed at reducing the incidental killing of dolphins. The result was the 1999 Agreement on the International Dolphin Conservation Program (AIDCP) which provided for limits on dolphin bycatch and observers to monitor compliance. Dolphin mortality was falling during the 1990s, and under the AIDCP, dolphin mortality associated with fishing operations has declined further (Perrin et al. 2002). Some have argued that the resolution of this dispute shows that it is preferable to conduct direct negotiations on global environmental issues with a view toward establishing an international agreement rather than trying to resolve them through the WTO. The WTO agreements pertain to international trade, not environmental protection or animal welfare, and, as noted by Marceau (2002), can only adjudicate disputes in terms of provisions that are specifically included in the WTO agreements. In considering the relation between WTO and human rights law, Marceau argues that if the WTO were to attempt to enforce rules that are not included in its agreements, it would be altering the WTO provisions and such modifications require the prior agreement of all member states. This does not, of course, exempt nations from their obligations under other international laws (on human rights or the environment). It simply means that the

WTO is not the appropriate place to adjudicate conflicts related to these obligations. In the case of the tuna-dolphin dispute, the problem that led to the imposition of trade restrictions was largely resolved by agreements made outside the WTO.

The AIDCP also includes provisions for the labeling of canned tuna as “dolphin safe” (Trujillo 2012). The United States did not adopt the AIDCP standards, relying instead on standards defined in the US Dolphin Protection Consumer Information Act (DPCIA). The DPCIA standards are more demanding than those in the AIDCP and this led to a new DS panel convened to adjudicate rules on labeling traded tuna as dolphin safe. The panel found that while the US labeling system was not discriminatory, it did restrict trade more than is necessary to accomplish the objectives (Trujillo 2012). The panel also noted that the US scheme may actually cause greater harm because it focuses on fishing methods rather than on dolphin protection *per se*. Under the DPCIA, the dolphin-safe label is reserved for tuna caught with methods that do not involve using dolphins to locate schools of tuna (Trujillo 2012). These alternative methods may lead to greater by catch of other species including sea turtles, sharks, and other types of fish (Guernsey 2010). Mexico and the United States both appealed the panel report and the Appellate Body subsequently reversed some of the findings. The final report adopted by the DSB in June 2012 determined that US dolphin-safe labeling provisions discriminated against Mexico and the United States has agreed to modify its laws to comply with the ruling (WTO 2012d).

One of the issues raised in this case is the question of whether WTO rules apply to “process and production methods” (PPM) or only to final products. Basic WTO principles require that countries apply the same trade policies to all members (the principle of most favored nation status) and that “like” products should be treated the same (Matteotti and Nartova 2011). Tuna caught with methods that harm dolphins are indistinguishable from tuna caught with dolphin-safe methods. This suggests that the two types of tuna

are like products and this would mean that they cannot be subject to different trade restrictions. For environmentalists, this misses the point entirely as environmental problems are often associated with production methods. Domestic regulations that prevent or constrain the use of particular production methods (limits on agricultural chemical applications, restrictions on the use of growth-promoting hormones in livestock production, cage-size requirements for laying hens, etc.) raise the costs of domestic producers who may not be able to compete with cheaper products imported from foreign suppliers not subject to these regulations. One way around this problem is to implement labeling systems although, as in the case of dolphin-safe labels, such systems may still be open to challenge if they are structured in ways that favor domestic over foreign producers. It should be noted that governments in developing countries often oppose the incorporation of environmental mandates in trade law because they understand that it may be difficult or impossible for them to comply with environmental and social standards developed in high-income countries that are incompatible with the economic and environmental conditions they face.

Discrimination was at the heart of another controversial DSB ruling. To protect several species of sea turtles listed under the US Endangered Species Act, the United States requires that shrimp trawlers deploy nets with “turtle excluder devices” (TEDs) that allow sea turtles to escape. Foreign suppliers of shrimp have to receive certification that they are complying with this requirement as well. In 1997, India, Malaysia, Pakistan, and Thailand filed a complaint arguing that the US certification system was discriminatory. In its final report, the Appellate Body went out of its way to emphasize that measures to protect sea turtles such as those of the United States are entirely legitimate under GATT Article XX which lists exceptions to WTO rules restricting the use of trade barriers (WTO 2012e). It did find, however, that the United States was discriminating against the four complainants because it offered countries in the Caribbean technical support in complying with the US requirements, support that was not available to the complainants. The United States

has revised its certification guidelines to comply with the ruling (WTO 2012e).

Conclusion

Decisions of the DSB are tied very closely to the wording in the texts of the international trade agreements adopted by the members of the WTO. Some of these decisions have come under fire because they seem to overrule legitimate national policies and standards on social and environmental issues. WTO supporters note that exceptions to restrictions on the use of trade barriers are allowed in the WTO texts. Such exceptions have to be structured in ways that do not favor domestic producers over foreign suppliers. Critics of WTO dispute resolution argue that, in fact, economic and commercial interests are usually given priority over environmental and social concerns despite the language on exceptions in the WTO texts. Arguing cases before the DSB is costly and requires experience and expertise and this may limit the ability of low-income countries to participate in the DS process raising issues of fairness and discrimination.

WTO GMO Dispute: Implications for the SPS Agreement

Introduction

In recent decades, global flows – whether of goods, services, capital, pests, chemicals, or greenhouse gases – have expanded together with new technologies, norms, and institutions that govern these flows. Several processes tend to denationalize what had been constructed as national in the modern era – policies, markets, capital, culture, and etc. – and to establish new global powers.

The World Trade Organization (WTO), which superseded the General Agreement on Tariffs and Trade (GATT) in 1995, is a central node of this newly emerging global order. Established to police trade barriers for compliance with internationally agreed rules, it also sets global norms,

such as standards of intellectual property and risk assessment for health and environmental issues. An agile institution, the WTO Secretariat is a relatively small bureaucracy linking hundreds of country representatives in Geneva.

While many international institutions have suffered a significant reduction in budget and political power in recent decades, the WTO has exerted a growing influence on nations throughout the world. Unlike most UN institutions and conventions, the WTO has a stringent enforcement capacity with efficient, fast dispute settlement procedures (Yerxa and Wilson 2005). The WTO's dispute resolution mechanism was employed over 400 times in its first 15 years of existence, as compared to the mere 300 disputes settled over the 45+ years of the GATT era. While only one GATT dispute settlement drew upon scientific experts, more than a dozen trade disputes did so in the early years of WTO (Pauwelyn 2002).

Globalization has prompted new means of knowledge production, validation, and appropriation alongside the burgeoning of new technologies. Conversely, science and technology craft and legitimize the new global arrangements. Under the WTO trade regime, science and law are articulated in specific powerful ways, expanding the scientific-expert authority to scrutinize any domestic regulations that impose trade barriers. The WTO's basic assumption is that free trade is good for the world, so no product ought to be excluded from free circulation unless proven dangerous through a risk assessment with scientific evidence. Hence trade disputes constitute a key arena for analyzing how the WTO jointly establishes global legal norms and what counts as relevant knowledge.

To understand how the WTO coproduces global norms and authoritative knowledge in practice, this essay examines the mobilization of scientific expertise in the dispute over genetically modified organisms (GMO). A complaint was filed in 2003 by the USA, Canada, and Argentina against the European Communities (EC) for operating a *de facto* “illegal moratorium” since 1999. The WTO Dispute Settlement Panel reached its findings on that complaint in 2006, largely supporting the plaintiffs' accusations against the EU.

This essay asks the following questions: How were particular forms of legal reasoning were elaborated through the judicial procedure? How does this matter for understanding the expanding power of WTO discipline over health and environmental policy-making in the world? What are implications for future trade disputes involving issues of human health and environmental protection? To answer those questions, the essay draws upon interviews with staff from the WTO Secretariat, parties to the dispute, as well as scientific experts and also publicly available documents and unpublished correspondence between the Secretariat, the Panel, and parties.

Putting the Dispute into the SPS

After inconclusive attempts at diplomatic negotiation, in September 2003 the WTO's Dispute Settlement Board appointed a Dispute Settlement Panel to review the case. WTO Panels are composed of three "judges," who are economists or trade lawyers by profession. The procedure is usually as follows: the Panel issues a report of findings, which parties can appeal, and then the appeal is heard by the Appellate Body, consisting of seven judges, which also files a report. This process is supposed to last no more than 15 months. However, in the GMO case, that process extended to almost 3 years, even without an appeal.

From the start of the dispute, the parties disagreed over its nature, its legal basis, and the relevance of science. The US Trade Representative (USTR) emphasized that European measures contradict the SPS Agreement's requirement that procedures should be completed "without undue delay," thus posing unjustified trade barriers (USTR 2004a, p. 5). The European Commission Legal Services justified regulatory delays by mentioning scientific uncertainty about environmental and health risks. To avoid the narrower SPS disciplines, which would limit any precautionary approach, the Commission argued that the WTO Agreement on Technical Barriers to Trade (TBT) and the Cartagena Protocol on Biosafety also should be reference points for judging EC

regulatory procedures. As early as 2004, however, the Panel had decided to frame the GMO dispute within the SPS Agreement alone, thus rejecting the EC's broader framing (Peel 2006).

To fit the entire dispute into the SPS, the Secretariat and the Panel redefined the ontology of GM crops within a relevant risk category. Originally the SPS Agreement targeted *epizootic and epiphytic* diseases – which were seen as risks to "human, animal, and plant life or health" – that may justify national measures limiting trade. As its first move, the Panel classified any environmental harm, including threats to biodiversity, under the SPS category of risks to "animal and plant life or health" (WTO 2006, paragraph 7.219). Secondly, the Panel cast GMOs as SPS agents: GM crops were redefined as "pests" (*transgene* escape hence becoming a "pest effect") or as "invasive species." Transgenes were recast as "food additives." GM pollen became a kind of "animal feed" because it could be ingested by bees (WTO 2006: paragraphs 7.225–7.299). Within the latter move, EC regulations on GMOs become SPS measures applied to protect human life or health from risks arising indirectly from the entry, establishment, or spread of weeds *qua* "pests" (WTO 2006, paragraph 7.360).

With those two ontological moves, the Panel established a particular link between GMOs' biological identity as ecological agents and GMOs' legal identity as subjects of SPS rules. Some of these new constructs contradicted definitions from the very international expert bodies that the SPS Agreement itself had designated as global benchmarks for regulatory standards. For instance, the Panel's framing of transgenes as "food additives" diverged from Codex Alimentarius' definition of "food additives" as additions made "in the manufacture" stage of food production. Nevertheless, the Panel argued that in the special case of "plant production," substances intentionally added at the stage of seed development and production could be reasonably considered to be substances added in the manufacture of the food plant, if the substances are present in the harvested plant as a component or affect the characteristics of the harvested plant (WTO 2006, paragraph 7.299).

The Panel hence created new legal ontologies for GMOs and related ecological effects to make them amenable to SPS disciplines. This SPS plot, in turn, constrained how scientific advice would be mobilized and performed in the dispute settlement procedure.

Framing Questions for Experts

In August 2004 the Panel announced its decision to seek expert advice, as in previous disputes involving the SPS Agreement. Once the Expert Panel members were selected, they were invited to express their views on specific questions, “solely for the purpose of assisting the Panel in its limited task of making findings of *fact* for purposes of these disputes” (Unpublished Terms of Reference, WTO Secretariat, September 2004).

During autumn 2004, the Panel and parties exchanged views on the questionnaire that would be sent to the experts. The final version included 114 questions. One quarter addressed general risk issues, such as sanitary risks related to genetic markers for antibiotic resistance, toxicity of Bt insecticidal crops for humans and nontarget animals, and invasiveness of herbicide-tolerant crops. In line with the Panel’s SPS framing, most questions focused on the scientific basis of the 27 regulatory delays and 11 national bans.

The US proposed to amend the initial draft questions in order to increase the burden of evidence on the Commission to demonstrate clearly that such a scientific basis existed. It also argued that:

... even if evidence of risks exists, an SPS measure must be ‘based on an assessment, as appropriate to the circumstances, of the risks.’ Furthermore, evidence of ‘existence’ of risk is not dispositive to the application of Article 5.7. Instead, the ‘relevant scientific information’ with regard to the risk must be insufficient. (unpublished correspondence, USA to Panel, September 24, 2004)

For instance, the USA proposed to ask the experts about all of the disputed delays or bans in which extra data had been requested from the companies on the potential risks associated with their products: “Is there any basis to expect that [this requested data] would identify any adverse effect that had not previously been identified?”

(USTR 2004b, p. 59). Such questions strongly shifted the burden of evidence to the Panel to demonstrate that extra data were necessary as well as feasibly obtainable.

By contrast, the EC sought to broaden the experts’ role. It posed questions highlighting uncertainties and limitations of scientific knowledge during the decade before the plaintiffs filed their complaint in 2003. The EC’s strategy was thus to emphasize knowledge gaps and uncertainties within scientific knowledge – understood as evolving over time, with much dissensus among scientists. The extra questions aimed to focus the experts’ attention on temporal changes. As the EC later reiterated, “We should not forget that we are looking at the science at that time” (WTO 2006, Annex J, paragraph 437). By engaging experts in a reflexive historicization of scientific knowledge, the EC strategy demonstrated how science was coevolving along with regulatory concerns.

In such ways, the Commission framed the dispute as a debate on past decisions made with knowledge at the time, which was then – but less so now – uncertain and thus insufficient for risk assessment. This historical narrative provided a way to manage the tension between the EC’s international and domestic agendas. The Commission Legal Services could defend the EC’s regulatory sovereignty, while also limiting member states’ scope to continue the de facto moratorium (Levidow and Carr 2010, pp. 156–159).

In the context of the dispute, the Commission’s strategy also aimed to broaden the notion of risk assessment by emphasizing divergent scientific views as evidence of uncertainty. In the beef hormone dispute, the Appellate Body had stated that:

[SPS Agreement] Article 5.1 does not require that the risk assessment must necessarily embody only the view of a majority of the relevant scientific community ... governments may act in good faith on the basis of what, at a given time, may be a divergent opinion coming from qualified and respected sources. (WTO 1998, paragraph 194)

In this understanding of the Appellate Body, a minority scientific view can justify a precautionary measure (SPS Art. 5.7), without needing a

formal “risk assessment” required by SPS Article 5.1 (Boisson de Chazournes et al. 2009).

The final version of the questionnaire accommodated the USA’s stringent view of the legitimate basis for regulators to adopt provisional measures under SPS Article 5.7. Many questions challenged the evidence for regulatory delays or bans, by asking experts the following: was there enough information to make a proper risk assessment as required by Article 5.1 before taking a precautionary measure under Article 5.7? Was the additional information requested really necessary to ensure the safety of the product? Or could not a “technical deficiency” be mitigated by providing other available safety information? Such questions pressed experts to challenge the Commission’s defense arguments, thus eliciting expert opinions that could both be cast as “scientific” and be used along SPS lines of legal reasoning.

Expert Disagreements on the Panel’s Questions

In the dispute settlement process, science was deeply framed by the WTO setting and a narrow interpretation of the SPS Agreement as the basis for judging the defendant’s regulatory practices. On the one hand, in the SPS Agreement, Article 5.1 requires that any measure restricting trade must be based on a risk assessment.

Members shall ensure that their sanitary or phytosanitary measures are based on an assessment, as appropriate to the circumstances, of the risks to human, animal, or plant life or health, taking into account risk assessment techniques developed by the relevant international organizations (WTO 1994).

On the other hand, Article 5.7 leaves some room for precautionary measures in the face of scientific uncertainty:

In cases where relevant scientific evidence is insufficient, a Member may provisionally adopt sanitary or phytosanitary measures on the basis of available pertinent information, including that from the relevant international organizations In such

circumstances, Members shall seek to obtain the additional information necessary for a more objective assessment of risk and review the sanitary or phytosanitary measure accordingly within a reasonable period of time. (WTO 1994)

The Panel’s questions directed the experts to scrutinize EC regulatory practices, especially in relation to the above criteria in the SPS Agreement. Scientific experts sometimes expressed divergent views, especially on the state of scientific knowledge and its adequacy for risk assessment. As in the case of molecular characterization mentioned above, for each risk issue, some members declared that the available knowledge was already sufficient for a favorable risk assessment. According to more cautious experts, however, available scientific knowledge in the late 1990s had not always been sufficient. For instance, one expert regarded the French rejection of herbicide-tolerant oilseed rape as “compatible with the tone of the SPS Agreement” (WTO 2006, Annex I-4, paragraph 657).

The plaintiffs asked particular experts whether the EC defendant’s delays or bans were the only way to manage scientific uncertainty and whether the additional information the defendants requested from companies was essential and if there were alternative ways to manage the potential risks. These questions pressed the experts to comment on risk-management issues. For example, the Panel and plaintiffs posed questions about whether the EC procedures delayed product authorizations by requesting extra molecular data. In response, two experts argued that detection methods were not a necessary component of risk assessment (WTO 2006, Annex J, paragraph 22).

Giving the Panel’s Verdict

The Panel’s findings focused on the defendant’s procedures: between 1999 and 2003 the EC had applied a general de facto moratorium, which led to its failure to complete regulatory procedures for 24 applications (out of 27 targeted by plaintiffs) without “undue delay,” thus violating Article 8 and Annex C of the SPS Agreement. Additionally, the nine national safeguard measures (bans)

violated SPS Article 5.1's requirement for a "risk assessment."

For both categories of complaint, the Panel gave the EC's advisory body a decisive role, while maintaining distance from any particular judgement by scientific experts:

EC committees issued opinions on each product and also reviewed the arguments and the evidence submitted by the member State to justify the prohibition and did not consider that such information called into question its earlier conclusions. The Panel thus considered that sufficient scientific evidence was available to permit a risk assessment as required by the SPS Agreement [Article 5.1]. Hence in no case was the situation one in which the Panel had been persuaded that the relevant scientific evidence was insufficient to perform a risk assessment, such that the member State might have had recourse to a provisional measure under Article 5.7 of the SPS Agreement. (WTO 2006, p. 1068, paragraph 8.09)

In that way, the Panel rejected the defendant's main argument, ostensibly on legal-procedural grounds. The EC had cited SPS Article 5.7 as a basis for precautionary measures due to scientific uncertainties, as evidenced by disagreements among the scientific experts during the dispute procedure as well as the wider risk debate. By contrast, the Panel interpreted SPS Article 5.7 as a legitimate basis for a provisional restrictive measure *only* when the relevant scientific evidence was insufficient to perform a proper risk assessment under Article 5.1.

For that legal issue, the Panel deferred to favorable EC risk assessments – such as those from the Scientific Committee on Plants and Scientific Committee on Food, whose earlier opinions had declared that information was adequate for a risk assessment on GM products relevant to the WTO dispute. Moreover, given the existence of official EU risk assessments, this placed a retrospective burden of evidence on EU member states for an alternative risk assessment to demonstrate the inadequacy of evidence at that time. In this regard, the Panel cited the SPS Agreement, which defined a risk assessment as "the evaluation of the likelihood of entry, establishment or spread of a pest or disease within the territory of an importing Member . . . , and of the associated potential biological and economic consequences" (WTO 1994, Annex A(4)).

The Panel did not explicitly judge whether EC scientific committees' opinions fulfilled that definition, but it did judge that national objections failed to do so. With the Panel's narrative of "sufficient evidence available," any scientific uncertainties and scientific dissensus were cast as irrelevant. This excluded the EC's narrative of science as historically contingent and contested.

Implications for the SPS Agreement

The Panel made substantive claims – for example, by innovating ontological categories (GMOs are pest, transgenes are food additives, etc.), by asserting that antibiotic markers genes are not dangerous, or by disregarding uncertainties that did not fit its narrow model of risk assessment. But these substantive judgements were not acknowledged as such. They were represented either as dictionary-based elaboration of terms and definitions in the SPS Agreements or else as a purely legal review of the EC's regulatory procedures, rather than as an engagement with scientific knowledge. Hence it seemed pointless to address substantive risk issues in the findings.

While previous Panels' findings in SPS disputes had reviewed both defendants' regulatory practices on substantive grounds and the opinions of scientific experts, the GMO Panel chose a different strategy. Its findings focused on the defendant's regulatory procedures, while avoiding any serious discussion of expert claims. This procedural turn was later reinforced by the Appellate Body's 2008 ruling which criticized the Hormones II Panel for having "reviewed the scientific experts' opinions and somewhat peremptorily deciding what it considered to be the best science" (WTO 2008, p. 612; Peel 2010, p. 216).

This shift may be understood in a political context where previous Panels' engagement with scientific risk issues had been criticized by anti-globalization activists, EC officials (Christoforou 2000), and scholars (Busch et al. 2004). The WTO was even warned against becoming a new "trans-science organization," thus undermining regulatory pluralism through a false, narrow conception of science (Walker 1998). Facing such criticism,

especially in the hot social-political context of the GMOs dispute, WTO decision makers found apparently less intrusive means to review the risk issues as a basis for their decisions. Hence the procedural turn in SPS jurisprudence constituted a significant shift in the WTO's formation of knowledge and norms.

As pioneered in the GMO dispute settlement, the procedural turn constructs both an interface and boundary between science and law. The legitimacy of the judgement rests on its "science-based" imprimatur, hence mobilizing scientific experts and scientific knowledge in the dispute settlement arena. Yet this expertise is framed in a way that allows WTO judges to avoid any explicit engagement with scientific knowledge. Under a procedural requirement for a "risk assessment," the Panel applied a stringent standard of review to the defendants' substantive risk claims. In several cases involving technical issues, by contrast, US courts have operated a legal epistemology whereby judges explicitly engage with scientific claims in order to separate sound science from junk science or marginal scientific views (Jasanoff 1995; Edmond 2002; Leclerc 2007). Such explicit engagement can also be found in previous SPS findings (Peel 2010, p. 254).

As this case illustrates, the WTO settlement process mobilizes scientific expertise in particular ways that can achieve multiple aims: it recruits a source of credibility from the scientific arena, reinforces the standard narrative of a "science-based" trade discipline, and constructs a new scientific expertise for the main task – namely, challenging trade restrictions for being unduly cautious. Moreover, by operating a procedural turn in the WTO's way of knowing, the Panel now keeps implicit its own judgements on substantive scientific issues. The decision makers' engagement with scientific aspects therefore becomes less explicit and less accountable.

Summary

The World Trade Organization (WTO) dispute settlement procedure is a key arena for establishing global legal norms for what counts

as relevant knowledge. As a high-profile case, the WTO trade dispute on GMOs mobilized and appropriated scientific expertise in somewhat novel ways. As shown above, the Panel interpreted the SPS framework as a requirement for "risk assessment" – quantifying likelihoods and consequences and imposing extra burdens upon the defendant to produce evidence. By imposing "the narrowest applications to date of the notion of SPS risk assessment" (Peel 2010, p. 244), the WTO Panel further globalized a "science-based risk assessment" narrative that had emerged during the USA's Reagan administration (Jasanoff 2011).

Early on, the Panel put the dispute under the Sanitary and Phytosanitary (SPS) Agreement through a new legal ontology; it classified transgenes as potential pests and limited all environmental issues to the "plant and animal health" category. For the SPS framing, focusing on the defendant's regulatory procedures, the Panel staged scientific expertise in specific ways that set up how experts were questioned, the answers they would give, their specific role in the legal arena, and the way their statements would complement the Panel's findings.

Moreover, the Panel operated a procedural turn in WTO jurisprudence by representing its findings as a purely legal-administrative judgement on whether the EC's regulatory procedures violated the SPS Agreement. Meanwhile the Panel kept implicit its own judgements on substantive risk issues. As this case illustrates, the WTO settlement process constructs a new scientific expertise for the main task – namely, challenging trade restrictions for being unduly cautious.

Introduction

While it is possible to trace the roots of the phrase “you are what you eat” to early Christianity where the body and the blood of Jesus Christ were represented by bread and wine (Gilman 2008), the phrase has become a token statement indicating a strong association between physical

well-being and eating, especially in the second half of the twentieth century. In contemporary parlance, “you are what you eat” refers to the idea that one’s eating habits determine and also are a manifestation of the health of the person in question. The phrase became a slogan of healthy eating in the English-speaking world during the 1940s through the efforts of nutritionist Victor Lindlahr with his radio broadcast and then his book entitled *You Are What You Eat: How to Win and Keep Health with Diet*, which sold around half a million copies (Levenstein 1993). During the 1960s, influenced by the hippie culture, healthy eating became synonymous with embracing a macrobiotic diet that involved whole foods (Gilman 2008). More recently, the phrase gave its name to a popular British TV show presented by nutritionist Gillian McKeith that aired between 2004 and 2007. The book derived from the show also had the same name and gained immense popularity with its emphasis on healthy eating as the key to overall well-being (McKeith 2005).

It can be argued that the statement has close associations with the shift from class to identity politics. Especially with the cultural turn of the 1980s, the phrase has been generally associated with individual choice. Its tone is also consistent with the individual agent’s responsibility and potential to define and redefine self through daily practices, thus also alluding to the character of the individual consumer. On a different level, the phrase also refers to the ways in which the chemical structure of the foods people consume affect the way in

which they act. By establishing a link between psychology and chemistry, this perspective attempts to explain the association between the food intake and human behavior such as the relationship between impulsive behavior and sugar intake.

The phrase also has close links with taste. Here, taste does not just refer to the physical appreciation of food, but rather it is both an individual and social experience, which is "...embedded within a social and cultural milieu involving habits, norms, rituals and taboos" (Pietrykowski 2004, p. 312). Taste is learned, and as a socially and historically embedded phenomenon, it is not just a marker of individual identity but connotes a class disposition as well. Therefore, consistent with the incorporation principle that Fischler conceptualizes, it is reasonable to suggest that the phrase "you are what you eat" covers a wide range of action, from the physical and biological relation with food, to the making of the individual consumer, to the delineating of class identity and membership (Fischler 1988). In this regard, what human beings eat helps sustain physical existence; it helps produce their identity both as an individual and as a member of a social group.

Despite the individualistic connotations that seem to indicate that the phrase belongs with contemporary and most often postmodern lifestyles, its roots lie very much with modernity. Below is an overview of the various incarnations of the phrase situated in their historical context. The overview helps demonstrate that to regard the phrase from an individualistic angle is not sufficient. Such a perspective overlooks the wider social, historical, and philosophical undertones of the phrase and as such provides grounds for the ethical/conscious consumer who should be responsible for his/her well-being while disregarding the limitations incurred by the ostensibly "all-knowing" consumer.

Brillat-Savarin and Gastronomy as Science

It is Jean Anthelme Brillat-Savarin who initially used the phrase in his *Physiologie du Gout, ou Meditations de Gastronomie Transcendante* (The Physiology of Taste) dating back to 1826. In the

fourth of the twenty aphorisms, which Brillat-Savarin claims will "...serve as prolegomena to his work and eternal basis to the science," he writes: "Dis-moi que tu manges, je te dirai ce que tu es" (Tell me what kind of food you eat, and I will tell you what kind of man you are) (Drayton 1994). Born into a family of lawyers, Brillat-Savarin did not owe his fame to his learned professions of law and politics. Rather, he became known as one of the most prominent pioneers of gastronomy of his times along with Grimod de la Reynière (Mennell 2008).

In general, Brillat-Savarin's work can be interpreted as part of an effort to establish gastronomy as a scientific as well as a modern discipline and to divorce it from earlier connotations of religious thinking that associated food with gluttony. He goes to great lengths to write a history of cooking, a philosophical one, where he traces the history of human beings' relation with food and cooking which he considers "the oldest of the arts" (Brillat-Savarin 2008a, p. 93). In this long history, humanity has arrived at a point, he argues, that the "word *gastronomy* has been revived from the Greek; it sounds sweetly in French ears, and although imperfectly understood, simply to pronounce it is enough to bring a joyful smile to every face" (Brillat-Savarin 2008a, p. 108). Brillat-Savarin (2008b) further expresses his dissatisfaction with the commonsensical definition of *gourmandism*, which he says exposes "an endless confusion between *gourmandism*...and *gluttony* or *voracity*" (p. 107). In this meditation, he first provides a long list of various definitions of the term. None of these definitions alludes to gluttony, and all of them point to a rational, moderate, and moral engagement with food. From a moral standpoint, he argues, *gourmandism* is a sign of "implicit obedience to the commands of the Creator," for it is God who gave us the appetite, and it is our duty to fulfill this to the best of our ability (Brillat-Savarin 2008b, pp. 107–108). Brillat-Savarin emphatically lists the numerous advantages of *gourmandism*. *Gourmandism* is advantageous not just for the individual but for societies in general. It helps industries stay alive and grow; it fosters connections among nations; overall, it is good for civilization. Brillat-Savarin's work can

be read as part of a discourse that emerged in the post-French Revolution era that associated gastronomy with the civilizing process. It was also during this period that the interest of the bourgeoisie in foodways increased as did the number of cooks who ran public eating places after their emancipation from the kitchens of aristocracy (Spang 2000).

Brillat-Savarin associates the rise of gastronomy with modernity, and his effort can be read as an attempt to inform diners of modern foodways (Ferguson 1998). The association of gastronomy with modernity was not limited to distinguishing eating from sin or merely positing it as a bodily function. The act itself was also what distinguished human beings from animals. As the second aphorism stated: "Animals fill themselves; man eats. The man of mind alone knows how to eat." Furthermore, Brillat-Savarin's focus on taste and his effort to locate the scope of gastronomy as a "sociological enterprise" that brought together the "scholar, the chemist, and the political economist" delineated this new science as a marker of collective identity. His experimental studies on eating habits of different social groups helped him work out the concept of the "gastronomic class" which closely associated with social class. It is in this line of thinking one should locate the statement, "Tell me what kind of food you eat, and I will tell you what kind of man you are." Not only does gastronomy allow for an informed approach to food and foodways, but it also helps establish a modern society with informed and enlightened citizens. Furthermore, when one has a better grasp of gastronomy and the history of eating, they will have essential tools to understand the character, the disposition, and the place of people within society. Food is much more than simply sustenance, it is the lens through which one can understand society and detect social dynamics.

Feuerbach's Sensationalism: "Man Is What He Eats"

Less concerned with the civilizing aspect of the food than with the philosophical endeavor to understand the ontological and epistemological

being of humankind in the era of enlightenment, Ludwig Feuerbach wrote "Man is what he eats" (*Der Mensch ist was er isst*) during the 1850s. Feuerbach wrote these words in his review of Moleschott's work on natural philosophy. The work entitled *Lehre der Nahrungsmittel* (Teachings on Foodstuff or Theory on Nutrition) had a considerable impact on Feuerbach, who was calling for an alliance with philosophy in lieu of religion in his scholarship. In search for this alliance, Feuerbach realized the significance of the mundane task of eating, and thus food, on human being's very existence. Later, his critiques took the phrase, which he had written toward the end of his scholarship, out of its context, and used it as an evidence that Feuerbach was placing too strong an emphasis on the significance of senses in gaining an understanding of the world and thus acting as a crude materialist (Hook 1994).

As Hook convincingly argues, it would be naive to state that Feuerbach was too excited to have rediscovered the wheel. Rather, his fascination of the link between something very tangible such as food and an ontological and epistemological stance of being and existence can be interpreted as a progressive step beyond knowing and making sense of the world through sensory experience. The phrase indicated that even sensory experience was not adequate, that humans needed something much more tangible yet more basic. Food is crucial here: not only does eating connect people to their surrounding world in ways in which other experiences cannot, but they simply have to eat not just to survive but also to be able to contemplate. The emphasis on food allowed the philosopher to unearth the indissoluble link between the mind and the body, the spirit, and the nature.

To overemphasize the statement "one is what one eats" without focusing on the larger body of ideas with which Feuerbach was engaging results in a lopsided interpretation of Feuerbach's work. It was Feuerbach's attempt to reject extreme forms of Hegelian idealism as well as absolute materialism. Transcending Hegelian idealism, not only did Feuerbach place the human being at the central stage and attempt to develop an anthropomorphic philosophy but also called for a new

philosophy divorced from religion. There were two implications of this perspective: Since this new philosophy put the human beings at the center, their needs and interests should be the focus of philosophy, not a futile attempt to get at a higher good or unattainable truth. The new philosophy, then, should find ways to free humanity from previous bonds and help attain political freedom. In this respect, the statement refers to an effort to ground human beings' well-being and freedom in their worldly dealings with nature, not in an abstract concept such as religion. Because "man is what he eats," it is through understanding and substantiating the link between the human being and nature can philosophy fulfill its end.

Secondly, situating the human being as the central focus and thus making him the active subject of making philosophy, not a conduit for getting at a larger truth, necessitated a refocus on the tools at his disposal, other than a Cartesian focus on mind, and thinking alone. It is true that when Descartes uttered the action of thinking, he implied something much more than mere contemplation, and he included sensing to his wide catalog of what thinking was comprised of. Feuerbach, on the other hand, conceived of a more direct connection between sensory experience and knowledge. Since man was the measure of all things, the way in which he could know the world would define the limits of his knowledge, therefore should be the only criterion of existence. For Feuerbach, the best and perhaps the only way man could know the world was through day-to-day dealings with nature to secure his livelihood. From this angle, the statement "man is what he eats" can be interpreted as the essential form with which the human being is embedded in and linked to the nature. The human being has to deploy nature in order to sustain, and this necessity imposes limits over knowledge of the world. Yet, this necessity also allows philosophy to locate its true task by placing the human being at the epicenter of this enterprise. This anthropocentric conceptualization of existence and knowledge also informed Feuerbach's scholarship on developing a psychological interpretation of religion, an area for which he is most well known, aside from Marx and Engel's "theses."

According to Feuerbach, neither idealism nor materialism could account for a full-fledged

conceptualization of the human being, his existence, and relation with the surrounding world since both perspectives overlook the true nature of human being, who is a creature of space and time and one who is active but at the same time limited and needy (Hook 1994). During the 1850s, in his later writings, Feuerbach looked for ways in which he could "...solve the traditional puzzle of mind and body through the idea of sensibility" (Turner 1996, p. 70).

Even though the temporal and spatial aspect of man's existence implicates his limits in getting a sense of the world in a more complete fashion, it also implies a promising potential since in this perspective, the world, or nature to be more precise, is not an isolated, external existence; thus, the relation to it becomes more meaningful as it is human's own making. This alludes to the creative nature of human beings which manifests itself as he handles the world surrounding him and implies a positive and creative engagement with nature rather than a subsumed one. One can further point out that it was this conception that Marx took as his departure point when accounting for alienation in his 1844 *Manuscripts* (Tucker 1978). It was Feuerbach's argument, later followed by Marx and Engels, that it was through human being's deployment of nature that he could get an understanding of his very existence and the world. Since humans are shaped by their needs and wants, food becomes an excellent choice through which the philosopher can understand how exactly they deploy nature and what we can learn from this about existence. Because it is through food and eating that nature, which has an external objectivity, becomes an internal subjectivity: "We are linked to external reality by our physiological needs, but this is an active linkage since external reality is literally appropriated and internalized by consumption" (Turner 1996, p. 185).

This rudimentary overview helps explain Feuerbach's enthusiasm for the nascent experimental studies on organic chemistry at his time. His willingness to incorporate Moleschott's work on nutrition can be interpreted in this light. "Sustenance," writes Feuerbach, "only is substance. Sustenance is the identity of spirit and nature. Where there is no fat, there is no flesh, no brain,

no spirit. But fat comes only from Sustenance. . . Everything depends upon what we eat and drink” (cf. Hook 1994, p. 268). This stance constitutes a challenge to the infamous Cartesian statement “I think, therefore, I am.” According to Feuerbach, for thinking to take place, being should be secured by the essential practice of sustenance. Therefore, thinking and being were inextricably linked (Turner 1996). What’s more, the kinds of food-stuff a human being consumes affect the ways in which he thinks. Thus, man is truly what he eats, for not only does eating ensure thinking, but also the substance of the act of thinking relies on the food consumed. For Descartes, the very fact that humans are thinking beings imply that God exists, for through the ability to think they can come to the realization of a perfect Being who implanted that thought in their mind. Feuerbach takes a step back and looks at the predicate of the act of thinking and situates sustenance right there. How is one supposed to think, if one does not get adequate sustenance?

While Feuerbach places man as a spatial and temporal being at the center of his philosophical endeavors, he does not leave his subject alone with his needs, wants, and limitations. One of Feuerbach’s significant claims was that was a social being. Thus, the very act of sustenance affects humans not just as individual beings but also as part of a collective. The food intake, Feuerbach argues, has a direct influence on the way in which human beings behave and feel. Since man is part of a larger group, how he feels and behaves also have repercussions on the overall behavior of the collective as a whole. From this assertion, Feuerbach makes a powerful inference about class behavior. Because working-class people mainly live on potatoes, he states, which lack essential nutritional qualities, they lack the strength to overthrow the wealthy, thus lead a revolution. He writes: “What is eaten turns to blood, the blood to heart and brain, to the stuff of thought and temperament. Human fare is the foundation of human culture and disposition. Do you want to improve the people? Then instead of preaching against sin, give them better food. Man is what he eats” (cf. Hook 1994, p. 270).

Summary

This overview of the origins of the phrase helps uncover its modern connotations. Unlike the emphasis on the ethical consumer citizen, who is responsible and is expected to be aware of her patterns of consumption and thus has everything at her own disposal to become healthy if only she has the willpower, the earlier incarnations of the phrase delineate either the structure of the field (as in the case of gastronomy as a modern discipline) which the subjects’ actions help build but also impose limitations on these actions or food as a conduit through which they can gain an understanding of the world and of ourselves. Even though this stance may be seen as less liberating for the individual, it is also worth mentioning that such conceptualization is more conducive to creating a collective character and even collective action. It is this angle that the individualistic interpretations of the phrase tend to overlook.

Youth Food Activism

Amy Kwan

Public Health, Department of Community, Society and Health, City University of New York (CUNY), School of Public Health, The Graduate Center, New York, NY, USA

Introduction

Young people have historically played a significant role in social movements. Currently, there is an increase in youth organizing, spurred in part by rising levels of inequality and an increase in the engagement of young people in civic activities. One such area that is witnessing increasing youth involvement is the social movement for food justice (Steel 2010), a rapidly growing movement focused on efforts to address and advocate for healthier, local, affordable, safe, equitable, sustainable food and food systems. With a rise in obesity and other noncommunicable, diet-related health problems and the persistence of food insecurity among many vulnerable populations, the involvement of young people in this movement has the potential to bring forth transformative changes to the food system and thus reduce

food-related health problems. This is particularly important as a disproportionate percentage of minorities bear the burden of obesity, food insecurity, and its health consequences.

This entry will first briefly describe the food justice social movement, with a focus on the United States, followed by a description of several ways in which young people are participating in and engaging with this movement. Given the dearth of literature on youth food activism specifically, this entry will end with a review of the pathways into and impact of youth activism in general.

Food Justice: A Social Movement

Gottlieb and Joshi define food justice as “ensuring that the benefits and risks of where, what, and how food is grown and produced, transported and distributed, and accessed and eaten are shared fairly” (Gottlieb and Joshi 2010). The Institute for Food and Development Policy/Food First defines food justice as “a movement that attempts to address hunger by addressing the underlining issues of racial and class disparity and the inequities in the food system that correlate to inequities to economic and political power” (Harper et al. 2009). These definitions illustrate the multifaceted nature of this relatively new, emerging social movement. Taking place on local, national, and global levels, this movement addresses diverse issues including economic development, hunger, race, racism, ethnicity, class, gender, and health and is closely tied with others such as the immigration, labor, gender equality, and environmental sustainability social movements (Holt-Gimenez 2011). This is reflected in the vision for the US food system that was laid out at the Institute for Agriculture and Trade Policy’s Food + Justice = Democracy conference held in the Fall 2012, which emphasized six food justice principles: (1) historical trauma; (2) local foods, community development, and public investment; (3) food sovereignty; (4) land; (5) labor and immigration; and (6) toxic-free and climate-just food system.

The food justice movement can be thought of as comprising several separate movements, for

instance, movements focused on production (e.g., local, organic, safe, fair production), consumption (e.g., school food, anti-marketing), and both production and consumption (e.g., farm bill, food security). The common goal of these movements is to have a “food system that promotes the health of people as well as the environment,” (Nestle 2009) or conversely, that “today’s food and farming economy is ‘unsustainable’ – that it can’t go on in its current form much longer without courting a breakdown of some kind, whether environmental, economic, or both” (Pollan 2010).

The issue of food and health has thus been transformed into a burgeoning food justice movement, with a growing number of active and visible advocacy groups protesting the practices of big agricultural corporations, widely released films and film festivals, books (e.g., *Fast Food Nation*, *The Omnivore’s Dilemma*), and primetime TV shows starring celebrity chefs (e.g., *Jamie Oliver’s Food Revolution*). A growing critique of this mass media attention on food, however, is its predominant focus on individual-level behavior and a lack of focus on the role of politics and social justice (Guthman 2007). Along these lines, researchers have recently again called attention to the important role of social influences on health and health inequities. Among the fundamental determinants of health conditions studied are income inequality, poverty, racism, and lack of opportunities for participating in democratic decisions (Braverman et al. 2011; Rogers et al. 2012). For many of these, social movements and activism have been identified as a promising solution (Birn 2009), highlighting the importance of understanding how and why social movements arise in response to health problems.

In public health, there has been a major push to address food and food policies in order to reduce health inequalities around diet-related illnesses and improve public health. Some examples include policies to increase access to healthy foods and decrease access to unhealthy foods (e.g., zoning of fast food restaurants, limits on advertising) and programs to engage young people and community members in skills-based learning, such as community gardening and cooking. The impact of these approaches, while

successful on some levels, has yet to dramatically transform the landscape of food environments. One promising avenue for realizing transformative change is through youth-led advocacy and organizing (Millstein and Sallis 2011).

Youth Organizing: Overview

The field of youth organizing has garnered attention from an array of disciplines, including sociology, psychology, social work, education, and public health. Given its multilevel, intra-, and interdisciplinary approach, numerous theories and concepts have been used to describe and operationalize the processes and outcomes of youth organizing, including youth empowerment, youth development, civic engagement, and socio-political development (Christens and Kirshner 2011). The Funders’ Collaborative on Youth Organizing (FCYO), a coalition working to advance youth organizing as a strategy for youth development and social transformation, defines youth organizing as “an innovative youth development and social justice strategy that trains young people in community organizing and advocacy, and assists them in employing these skills to alter power relations and create meaningful institutional change in their communities” (Funders’ Collaborative on Youth Organizing 2011). Despite diverse theoretical and applied approaches, common features of youth organizing include focusing on youth-driven issues, challenging traditional norms around power, using collaborative approaches to social and systems change and collective decision-making processes, and being adult supported (Christens and Dolan 2011). Within this field, there is a continuum of youth participation, ranging from youth involvement in social activism to youth-driven activism within an adult-led movement to youth-led organizing.

The issues that are addressed in youth organizing settings are generally locally based, youth-selected, and contextualized within larger political and social justice frameworks (Christens and Kirshner 2011). A 2010 survey of 160 youth organizing groups in the country found that the most

common issues addressed among youth organizing groups include education justice/education reform (65%), community and neighborhood improvement (50%), racial justice (50%), economic justice (38%), environmental justice (37%), and health (37%) – which included environmental work, in addition to food justice (Torres-Fleming et al. 2010).

Youth participation and leadership is crucial to public health, where leadership has been defined as “speaking out about injustice, and being prepared to take up the fight within our own field as well as in the broader society...and to contribute our specific expertise while recognizing that we have much to learn from the expertise of others” (Krieger 1990). Public health, a field rooted in the tenets of social justice, tries to address the multiple and complex pathways to disadvantage and works towards improving health of populations and reducing health inequalities by breaking down ethical, political, economic, and social barriers to equality (Beauchamp 1999; Gostin and Powers 2006). In a recent review of the World Health Organization’s report *Closing the Gap in a Generation* (CGG), Birn (2009) calls for greater political activism and advocacy in public health practice and urges more attention to the historical and present role of social justice movements in reducing health inequity. For example, researchers are beginning to point to social movements and in particular building on current movements with similar behavioral end goals, as a strategy for addressing obesity (Dietz and Robinson 2008; Robinson 2010). Such an approach shifts the focus from targeting individual-level behavior and towards elements of social movements (e.g., identity formation, social interaction) that may result in health benefits and obesity prevention as a “side effect” (Robinson 2010). Organizations dedicated to positive youth development and youth leadership embody these beliefs and practices of political action by engaging young people in understanding historical and current political, social, and cultural contexts. In this way, they seek to positively transform their communities, as can be seen with the food justice movement.

Youth and Food Activism

Rooted in Community National Network, a “national grassroots network that empowers young people to take leadership in their own communities” has created the Youth Food Bill of Rights, which states the following rights: (1) We have the right to culturally affirming food, (2) we have the right to sustainable food, (3) we have the right to nutritional education, (4) we have the right to healthy food at school, (5) we have the right to genetic diversity and GMO-free food, (6) we have the right to poison-free food, (7) we have the right to beverages and foods that do not harm us, (8) we have the right to local food, (9) we have the right to fair food, (10) we have the right to good food subsidies, (11) we have the right to organic food and organic farmers, (12) we have the right to cultivate unused land, (13) we have the right to save our seed, (14) we have the right to an ozone layer, (15) we have the right to support our farmers through direct market transactions, (16) we have the right to convenient food that is healthy, and (17) we have the right to leadership education.

While the food movement is generally new and burgeoning, there are numerous youth-centered programs, organizations, and activities working towards the goals of food justice. The diversity of the goals and issues of the food movement affords multiple ways to categorize food justice work and strategies for engaging young people. These include goals of working with young people, for example, nutrition education, skills and job training, and youth empowerment or leadership skills. This ties in closely with the consideration of level or degree of youth engagement within organizations – from offering education or services, to being adult led but youth engaged, to being fully youth led. Additionally, programs may focus on a specific area of the food justice movement, such as urban agriculture, community food access, institutional or school food, and food policy. Lastly, the reach and scope of youth food activism can range from large-scale, national-level organizations to classroom- and school-based programs.

More specifically, a 2007 report found that there were 151 youth in sustainable food systems programs in the United States, Canada, and Puerto Rico. Of the 41 organizations that responded to a survey, 95% manage agriculture or gardening education programs and 73% offer nutrition and health programs, while only 27% get involved in food policy legislation (The Food Project 2007).

Urban agriculture and sustainable farming offers ways for young people to learn how to grow food and become engaged in addressing local food production and food access. Such programs may offer opportunities in the form of internships or summer employment to young people to work in community gardens, school gardens, and farmers' markets while learning about food and nutrition, leadership, and social justice. Programs such as these emphasize job creation and training for young people, responsibility, leadership development, creation of safe spaces, and opportunities to contribute to their neighborhoods.

Programs working on community food access, on the other hand, may focus on food insecurity and health inequities through efforts like reducing the availability and consumption of unhealthy foods in poor, underserved neighborhoods. These efforts may involve conducting community food assessments to understand the availability of and access to food in different neighborhoods. These types of programs reflect the importance of youth and community-based participatory research and environmental and economic injustices as they relate to food and health.

Activism around school and institutional food is also a major area for youth involvement. There are national-level organizations (e.g., Real Food Challenge) working to advocate for and improve food procurement and food systems connected to universities and colleges. Elementary, middle, and high schools are also engaging young people to improve school food and cafeteria environments. Efforts may span local sourcing, availability of healthier and fresh foods, school gardens, and nutrition.

Youth activism in food policy is another form of youth involvement whereby young people are becoming involved in their local food policy

council, which is a group of representatives from diverse sectors of the food system that seeks to "identify and propose innovative solutions to improve local or state food systems, spurring local economic development and making food systems more environmentally sustainable and socially just" (Harper et al. 2009).

In addition to building and supporting the food justice movement, mobilization and engagement of young people in food activism fosters leadership and empowerment. In this way, the impact of youth activism extends beyond the individual activists and their specific issues into communities and societies (Sutton et al. 2006), forming critical social capital for public health and health-based social movements.

Factors Associated with Youth Engagement

Given the dearth of literature on youth food activism specifically, an overview of factors that influence how young people become involved in social justice work in general, and the impact of their work, is warranted.

Political activism is very much embedded in psychological, social, cultural, and political contexts. Children start developing an age-appropriate understanding of the world on a macro level well before adolescence. This includes perceiving realities of their world, hopes for the future, and how they want to be involved in shaping their futures (Chana 2007). In fact, civic engagement is a critical element of the transition between adolescence and adulthood, where during adolescence, young people start to become aware of political and social issues and join related groups and, during late adolescence, they start conceiving a plan for the future (Flanagan and Levine 2010). Key developmental phases of building leadership and fostering civic engagement include recruitment into youth organizing activities, skills development, formal education, and training (Ginwright 2010).

An interest in politics, often developed early in childhood or adolescence, can also be due in large part to the role of the family. Factors such as

political involvement, family values (e.g., responsibility, ethics), educational attainment, and exposure to social problems and inequities can sometimes lead young people into similar fields.

Beyond the role of family, an extensive evaluation of transformative youth development programs found that providing young people with equal opportunities and decision-making capabilities is crucial for effective personal and community-level change (Sutton et al. 2006). Key organizational factors that contribute to effective youth organizing include the fostering of agency and ownership, attention to self-identity, provision of adult support, and structures for opportunities. Organizations that link youth leadership development with community development and social change and offer hands-on and meaningful opportunities for action are also a powerful influence on the development of young activists (Shah 2011). Social justice-oriented and youth-oriented organizations offer a much-needed safe space and social venue for young people to develop a sense of critical and social analysis of inequality and to connect with others while doing so, thereby fostering a collective identity (Christens and Speer 2011; Watts and Flanagan 2007). As one sociologist noted, “merely joining an organization will not turn one into a political activist if the context of that organization does not provide the individual with the cognitive engagement, capacity for political discussion, and, most importantly, political network connections needed in order to take action” (Walker 2008).

Another organizational-level factor is the notion of social movement organizations (SMO), which are organized components and building blocks of a social movement that are oriented towards movement goals. Or as Lofland describes, SMOs are “associations of persons making idealistic and moralistic claims about how human personal or group life ought to be organized that, at the time of their claims-making, are marginal to or excluded from mainstream society – the then dominant constructions of what is realistic, reasonable, and moral” (Lofland 2009). SMOs offer a platform for which to understand how people become involved in social movements and activism. For example, the

community development organizations, school-based organizations, and youth-led coalitions described earlier could be considered social movement organizations for the food justice movement.

Impacts of Youth Activism

The potential beneficial individual-level outcomes of youth participation in social action are numerous. Increasing evidence demonstrates that young people who are actively involved in their communities in meaningful roles, such as engagement in advocacy and activism, have better developmental (e.g., social skills, teamwork, initiative, responsibility), educational (e.g., attainment, motivation, intentions to go to college), psychosocial (e.g., leadership, confidence), sociopolitical (e.g., critical awareness of power, increased sense of agency), and health (e.g., quality of life, locus of control, self-efficacy) outcomes.

Additionally, youth participation is viewed as a critical and powerful process for strengthening knowledge and transferrable skills (e.g., research, strategic thinking, public speaking) and addressing institutional and systems-level changes, such as health inequalities of young people. Those who take part in social action as youth have been shown to have stronger ties with their communities and a greater understanding of their own health status and behavior. This can lead an increased sense of empowerment, as well as improved health outcomes and the potential to become local health advocates (Christens and Dolan 2011; Suleiman et al. 2006; Syme 2000). It is important to note that these types of outcomes are not universal and the ways in which they differ by individual or experience need further exploration.

On a community level, the media and public consistently characterize young people with negative stereotypes – of challenging authority, succumbing to negative peer pressure, dealing with conflict, engaging in violence or other risky behavior, etc. (Camino and Zeldin 2002). This, in conjunction with few and inequitable opportunities for young people to be civically engaged, reinforces stereotypes that young people are

uninterested in and unable to engage with communities and participate in social change. Youth-serving organizations, however, can challenge these norms and shift how communities and adults consider young people by reframing the perception of youth as “problems” of society to “resources” or agents of change (Checkoway et al. 2005; Zeldin et al. 2000). An evaluation of youth organizations supports these findings. Youth who worked with adults and participated in decision-making processes within an organization positively altered adults’ perceptions of young people’s social and cognitive competence, responsibility, contribution, and commitment (Zeldin et al. 2000). While there are challenges with attributing specific community-level outcomes to young people in decision-making roles (as this requires a long-term assessment within and across multiple organizations and agencies) (Zeldin et al. 2000), changes in norms on all levels are critical for establishing conditions for policy change (Nathanson 1999).

Summary

The food justice movement is a rapidly growing social movement aimed at addressing and advocating for healthier, local, affordable, safe, equitable, sustainable food and food systems. Given the rise in obesity and other noncommunicable, diet-related health problems and the persistence of food insecurity among many vulnerable populations, the involvement of young people in this movement has the potential to bring forth transformative changes to the food system and thus reduce food-related health problems. This is particularly important as a disproportionate percentage of minorities bear the burden of obesity, food insecurity, and its health consequences. While this entry focuses on the United States, young people all over the world are engaging in this movement, identifying as food activists and transforming communities – through community gardening and sustainable farming, nutrition education, farmer’s markets, food policy councils, anti-marketing campaigns, policy advocacy, and much, much more.
